ABSTRACT

Acute tubular damage is a major cause of renal failure, especially at the early phase of kidney transplantation when ischaemia-reperfusion injury and cyclosporin toxicity may coexist. The latter's mechanisms are largely unknown. Using an mRNA microarray on microdissected tubules from a rat model of cyclosporin toxicity to describe its transcriptional epithelial-specific signature *in vivo*, we found that cyclosporin induces ATF4-dependent pathways and identified *Nupr1*, a gene induced by ATF4, as the most strongly upregulated. *Nupr1* expression was induced upon injury in cultured human tubular epithelial cells and in kidney transplants. Using *Nupr1*-deficient mice, we show that *Nupr1* protects the tubular epithelium from cyclosporin toxicity, preventing structural damage, apoptosis and ATP depletion. *Nupr1* decreased cell proliferation and limited protein synthesis in proximal tubular cells treated with cyclosporin. Finally, NUPR1 was also upregulated in models of ischaemia-reperfusion injury, urinary obstruction and hypertension. Taken together, these results suggest that epithelial expression of NUPR1 plays a protective role in response to injury after renal transplantation and, presumably, in other forms of acute tubular damage.

Keywords: acute renal failure / cell survival / ATP / injury response / transcriptomics

INTRODUCTION

Tubular damage is a major cause of renal failure, and both ischaemic and toxic tubular injuries are very frequent causes of acute and chronic renal failure.[1] The course of any renal tubular injury typically starts with loss of specialised function (e.g., proximal tubular cells lose the brush border and their ability to reabsorb low-molecular-weight proteins) and ends with cell death through necrosis, apoptosis or necroptosis.[2] Repair occurs through proliferation of the surviving epithelial cells and their redifferentiation into specialised tubular cells.[3]

Most kidney-transplanted patients are treated with calcineurin inhibitors, which cause vascular and tubular damage.[4] These drugs, mainly cyclosporin A (CsA) and tacrolimus, can initiate tubular lesions,[5, 6] but the exact mechanism is currently unknown. Calcineurin is a serine phosphatase involved in the dephosphorylation of various proteins and, most importantly, a family of transcription factors – the nuclear factors of activated T cells (NFATs). There are five of these; NFATs 1 to 4 are regulated by calcineurin, and NFAT5 is regulated by osmotic stress.[7] Calcineurin, by dephosporylating NFAT, allows it to enter the nucleus and begin its transcriptional activity. NFAT target genes involved in the inflammatory response have been extensively studied in lymphocytes, where NFAT acts as a transcriptional activator, but also as a repressor for some genes.[8] *In vivo*, CsA induces renal vasoconstriction and tubular lesions.[9] The spontaneous development in mice deficient for calcineurin A alpha of a renal phenotype reminiscent of cyclosporin toxicity indicates that the decrease in calcineurin activity is sufficient to trigger renal damage.[10, 11] Genetic deficiency of either cyclophilin or NFATc1 (i.e., the two substrates known to be inhibited by cyclosporin) is not sufficient to initiate tubular damage, but may increase it by impeding the tubular repair process.[12-14]

The mechanisms by which cyclosporin alters tubular function or repair are still ill-understood. Its vasoconstrictive properties on afferent arterioles might be involved *in vivo*, by causing subintrant ischaemia downstream.[4] A direct effect within the epithelium is also plausible since, like many xenobiotics, calcineurin inhibitors are metabolised by tubular epithelial cells. Endoplasmic reticulum (ER) stress is one hallmark of *in vitro* cyclosporin toxicity.[15-17] It is a complex phenomenon with antagonistic consequences.[18] The term refers both to the accumulation of misfolded proteins in the ER and to the molecular events triggered in response to this accumulation. The accumulation of misfolded proteins recruits the chaperone protein BiP, thus in turn activating double-stranded RNA activated protein kinase-like ER kinase (PERK), a kinase that phosphorylates the transcription factor EIF2alpha. EIF2alpha phosphorylation is the common end-signal of kinases activated by amino-acid limitation (general control non repressible 2, GCN2), viral infection (double-strand RNA-activated kinase), heme limitation (heme-regulated inhibitor kinase) and protein misfolding (PERK).[19] The biological role of EIF2alpha phosphorylation is to decrease protein translation in general, except for that of adaptive proteins, including ATF4, a master transcription factor. ATF4 induces the expression of adaptive genes. If sustained, however, ATF4-induced upregulation of protein synthesis eventually causes ATP depletion and cell death.[20] It is thus essential to control the ER stress pathway. Cyclosporin toxicity is known to be associated with impaired energy status and can be alleviated by ATP.[21] Together, these data strengthen the hypothesis that ER stress plays a role in cyclosporin-induced renal injury.

Our group has extensively studied the phenotypic changes observed in tubular epithelial cells from human kidney recipients exposed to cyclosporin and has repeatedly shown, in particular, that immunohistochemical staining of two mesenchymal markers, vimentin and beta-catenin, in tubular epithelial cells detects cyclosporin tubular toxicity at an early, reversible stage.[5, 22] We have also shown that the expression of these mesenchymal markers in tubular epithelial

cells of kidney grafts in patients treated with cyclosporin is associated with initial ischaemic injury and is predictive of further development of kidney fibrosis.[23, 24] To further investigate the mechanisms of CsA-induced tubular injury, we characterised the *in vivo* tubular transcriptomic changes that occur at an early stage of cyclosporin toxicity. Our findings point to a new response gene encoding nuclear protein, transcriptional regulator, 1 *(Nupr1),* which has a central role in the ER stress pathway. We show here that *Nupr1* is induced in several animal models of acute tubular damage and confers resistance to renal tubular damage in these animals presenting cyclosporin toxicity.

RESULTS

Cyclosporin induces tubular transcriptomic changes that are related to protein synthesis and stress.

We used laser microdissection coupled to an mRNA microarray to perform an *in vivo* comparative transcriptomic analysis of rat renal tubules exposed to either vehicle or nephrotoxic doses of cyclosporin (Figure 1, Dataset 1). Using a 1.5-fold threshold (with $P<0.05$ by t-test), we found that 179 genes were downregulated and 286 genes upregulated by cyclosporin (Dataset 1). The gene expression pattern confirmed that this transcriptomic analysis was limited to tubular epithelium, since the expression of endothelial (*Cd31*) and podocyte-specific (*Nephrin*) genes was very low (respectively 3 and 2 on a logarithmic scale ranging from 2 to 14). Markers specific to the proximal tubule (*Npt2a* and *Lrp2*) were very strongly expressed (12 on the same logarithmic scale), whereas *Aqp2*, a marker of collecting ducts, was expressed only moderately (7 on the logarithmic scale). None of these cell-specific markers differed between the cyclosporin- and vehicle-treated groups. In contrast, we found that known markers of tubular damage — *Havcr1* (aka *Kim1*) and osteopontin (*Opn*) — were

induced in renal tubules exposed to cyclosporin (3 to 7 for *Kim1* and 5 to 9 for *Opn* on the logarithmic scale). Figure 1 presents these expression data.

The pathway analysis using the Pathway Analysis using Logistic Regression (LRpath) identified significant changes in the expression of genes involved in five Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways: ribosome, protein processing in the endoplasmic reticulum, protein export, peroxisome, and terpenoid synthesis (Figure 1, Supplemental Table 1 and 2). Notably, searching the TRANSFAC® database for transcription factors associated with the observed transcriptomic changes did not identify NFAT or any other transcription factor. The first 3 pathways (ribosome, protein processing in the endoplasmic reticulum, and protein export), all involved in protein synthesis, showed overexpression in the CsA group, whereas the latter 2 (peroxisome and terpenoid synthesis) were underexpressed. This transcriptional signature of cyclosporin *in vivo* in the tubular epithelium is strongly reminiscent of the ATF4-dependent gene expression induced by tunicamycin (an ER stress inducer) *in vitro*.[20] Accordingly, we observed that nephrotoxic doses of cyclosporin consistently enhanced the level of ATF4 in renal tubular cells, as shown by immunohistochemical analysis of kidney sections from CsA-treated mice. Moreover, ATF4 was induced by CsA *in vitro* in cultured mouse tubular epithelial cells, as shown by western blot (Figure 2). Interestingly, *Nupr1*, an ATF4-responsive gene,[25, 26] was the gene most highly overexpressed (86 times) under cyclosporin in this microarray analysis (Supplemental Table 1). To our knowledge, the role of *Nupr1* in acute tubular damage has not previously been studied *in vivo*.

Nupr1 confers resistance to epithelial injury

To gain insight into the role of *Nupr1* in CsA nephrotoxicity, we translated our experimental model to mice. C57bl6/J wild-type (WT) mice showed evidence of epithelial toxicity with renal failure after 2 weeks of cyclosporin at doses between 50 and 100 mg/kg/day SC. A dose of 100 mg/kg/day induced acute kidney injury, weight loss, tubular damage, apoptosis and proliferation together with dose-dependent *Nupr1* induction by CsA and ER stress (Supplemental Figures 1, 2 and 3). We used *Nupr1* knockout mice to investigate the role of this gene in cyclosporin-induced renal injury. Although these *Nupr1*-deficient mice showed no spontaneous renal phenotype, the renal tubular lesions they developed when challenged with cyclosporin were substantially worse than those observed in WT mice. They had more tubular vacuolisation and dilation than their WT littermates (semi-quantitative score 2 [0.88-2.5] vs 0.5 [0.5-1], P= 0.009 for vacuolisation and 1.75 [0.5-2] vs 0 [0-0.5], P=0.003 for dilation, Figure 3 A, B, G, F). Accordingly, *Kim-1* mRNA expression was significantly higher in the cortex of *Nupr1*$^{-/-}$ compared with WT mice; a trend towards higher plasma urea levels in the *Nupr1*$^{-/-}$ mice was also observed, but did not reach statistical significance (Supplemental Figure 4).

The mechanism by which Nupr1 protects the renal epithelium involves cell survival but not decreased cyclosporin exposure, vascular reactivity or enhanced tubular repair.

Measurements of serum cyclosporin trough levels showed that the groups did not differ for cyclosporin exposure (Supplemental Figure 5A). Nor did the knockout mice differ from the WT in their expression of the *Il27* gene, a close neighbour of the *Nupr1* gene on the mouse genome and a potential regulator of cyclosporin-induced inflammation[27] (Supplemental Figure 5B). Measurements of aortic blood pressure and renal blood flow in *Nupr1*$^{-/-}$ and WT

mice after 5 days of cyclosporin (100 mg/kg/d SC) or 5 days of vehicle showed no haemodynamic effect of *Nupr1* (Supplemental Figure 5C-D).

After cyclosporin treatment, apoptosis, assessed by TUNEL, was more frequent in renal tubular cells from *Nupr1*$^{-/-}$ (18.5 [9.8-33.3] nuclei/field) than in WT mice (4 [1.75-6.5], *P*= 0.01) (Figure 3 E, F, J). This observation suggests that *Nupr1* protects tubular cells from death. Tubular proliferation assessed by Ki67 staining was again more frequent in the renal tubular cells of the *Nupr1*$^{-/-}$ (89.5 [55.5-117.3] nuclei/field) than WT animals (43.5 [33.3-56.5], *P*= 0.03) (Figure 3 C, D, I). Both tubular apoptosis and proliferative repair increased in the absence of *Nupr1*.

Nupr1 limits protein synthesis, proliferation and cell death, and preserves the energy status of epithelial proximal tubular cells during* in vitro *cyclosporin toxicity.

We used primary cultures of proximal epithelial tubular cells from *Nupr1* knockout and WT mice to investigate the effect of *Nupr1* on apoptosis under CsA treatment. In wild type cells, we measured ATF4 protein, *Nupr1*, *Atf4, Chop* and *Bip* mRNA expression before and after 1, 2, 3, 6 and 24 hours of cyclosporin exposure. All these parameters were induced already after one hour, with ATF4 protein induction being the strongest at this early time point, except *Bip* that was induced only after 3 hours (Figure 2C). *Nupr1*$^{-/-}$ cells had a higher level of ATF4 expression after CsA treatment than wild type cells (Supplemental Figure 6). Using a pulse of homopropargylglycine (a methionine analogue) to evaluate protein synthesis by immunofluorescence and flow cytometry, we showed that cyclosporin decreased protein synthesis in wild type cells but didn't do so in *Nupr1*$^{-/-}$ cells (Figure 4).

We measured cell proliferation using 3 different techniques: a simple cell count 48 hours after seeding various numbers of cells, continuous monitoring of cell density with xCELLigence technology, and BrdU incorporation (Figure 5, Figure 6A-B and Supplemental Figure 7). All

techniques showed that *Nupr1-/-* proximal tubular cells proliferated faster than wild-type cells. Treatment with CsA virtually abolished proliferation in wild-type cells, but only decreased proliferation in knock out cells (Figure 6A-B). Although proliferation was maintained, assessment by xCELLigence of CsA-treated *Nupr1-/-* cells showed a decrease in cell density, suggesting cell death.

Similar to CsA renal toxicity *in vivo*, 5 µg/mL CsA induced cell death, with more dead cells in *Nupr1-/-* cells compared to WT cells (Figure 6C).

We investigated the effect of *Nupr1* on the energy status of proximal tubular epithelial cells by measuring ATP and ADP in *Nupr1*$^{-/-}$ and WT cells incubated for 24 hours with or without 1 µg/mL CsA (Figure 6D). ATP/ADP ratio were lower in the *Nupr1-/-* mice compared to wild type mice. Moreover, the ATP/ADP ratio decreased still further after cyclosporin was added. The effect of *Nupr1* on the ATP/ADP ratio was explained mainly by a fall in ATP, although ADP increased slightly as well (Supplemental Figure 8).

Rescuing *Nupr1* deficiency by transfecting a *flag-Nupr1* transgene into *Nupr1-/-* proximal tubular cells did inhibit proliferation (less cells in S phase, and more cells in G2/M) in cells expressing the transgene, thus confirming the instrumental role of *Nupr1* in proliferation and apoptosis (Figure 7 and Supplemental Figure 9).

Nupr1 induction is relevant to other models of kidney injury in mice and in human kidney transplantation.

To determine if *Nupr1* was specifically upregulated after CsA treatment, we measured *Nupr1* mRNA in kidney cortices of mice in control conditions and after ischaemia-reperfusion injury, unilateral ureteral obstruction, and angiotensin II-induced hypertension. As shown in Supplemental Figure 10, we found that *Nupr1* was upregulated in each of these different experimental models. This finding suggests that *Nupr1* may exert its protective effects in many forms of kidney injury.

We studied the expression of *Nupr1* in cultured human renal epithelial cells. Increasing the cyclosporin concentration dose-dependently induced *Nupr1* mRNA expression in human proximal tubular cells (Figure 8A). We also performed immunohistochemical analysis for NUPR1 on normal kidney (stable renal allografts) and on injured kidney (pre-implantation biopsies from donors with acute tubular necrosis and allografts undergoing acute tubular necrosis or allograft dysfunction). Using multiple stainings for NUPR1, Megalin and nuclei, we found that, in normal kidney, NUPR1 expression was absent in nuclei from renal proximal tubules. Conversely, in injured kidneys, NUPR1 was strongly expressed in many nuclei from renal proximal tubules. (Figure 8B-F)

DISCUSSION

Kidney resistance to injury varies greatly,[28] as exemplified by cyclosporin toxicity; it is widely prescribed to patients in standardised conditions and results in variable toxicity, depending on the dose, on additional insults, and on the patient's own characteristics.[4] Several genes involved in xenobiotic detoxification have been suggested as risk factors for calcineurin inhibitor nephrotoxicity.[29] Cyclosporin nephrotoxicity nonetheless remains poorly understood, especially its *in vivo* effect on renal tubular epithelium. Our investigation provides the first description of this drug's genome-wide transcriptional effect there. Our primary hypothesis was that calcineurin inhibition would cause toxic effects by inactivating NFAT, a pleiotropic transcription factor. NFAT-induced genes (e.g., *Il2*) are expected to be downregulated by cyclosporin through calcineurin inhibition.[8] Other genes have been shown to be repressed by NFAT (e.g., *Cdk4*) and might thus be enhanced under cyclosporin treatment.[8, 30-32] Interestingly, one of the genotypes at risk of cyclosporin toxicity is a low-activity variant of *Cyp2c9*,[29] the gene most downregulated by cyclosporin in our data (Figure 1). However, the *Cyp2c9* promoter contains no NFAT-response-element,[33] and neither the NFAT nor the calcineurin pathways were modified by cyclosporin on a transcriptional level

in our data. These seemingly contradictory results can be interpreted in two ways: 1) the calcineurin and NFAT pathways in the tubular epithelium (our data) are very different from these pathways in the lymphocytes (previously published data); thus, bioinformatic tools like LRpath do not link our data to calcineurin and NFAT, and 2) the pattern of gene expression we observed is not directly caused by the inhibition of the calcineurin and NFAT pathways. Other substrates of calcineurin might be involved, or a secondary transcriptomic response to injury. This pattern is reminiscent of the genes induced by ATF4, a master transcription factor that orchestrates the expression of stress genes, including *Nupr1* and other stress related genes that were overexpressed in our analysis, like *Asparagine synthetase* and several aminoacyl-tRNA-synthetases. ATF4 induces a transcriptional program that upregulates the energy-expending mechanisms of protein synthesis potentially leading to cell death.[20] Decreased ATP levels are instrumental in cell death, whether due to diminished ATP production (decreased fatty acid oxidation) or to enhanced ATP consumption (increased protein synthesis).[20, 34] Here, after administration of toxic doses of cyclosporin *in vitro* and *in vivo*, renal tubular cells expressed ATF4-dependent pathways associated with decreased expression of peroxisome genes and increased rates of protein synthesis, energy depletion and cell death.

Nupr1, essentially unstudied in renal diseases, is a chromatin-binding protein induced by various epithelial stresses and has important properties: it is anti-apoptotic and anti-inflammatory, and it regulates cell proliferation.[35] Its expression is instrumental in endothelin-mediated mesangial hypertrophy.[36] Because *Nupr1* is an early stress response gene induced by ATF4 in the renal tubular epithelium and protects tubular cells from cell death,[25] we hypothesised that it might protect against apoptosis by preserving the cell energy status.

We found that *Nupr1* was strongly expressed during cyclosporin-induced renal epithelial lesions *in vivo* and *in vitro* and that it exerted a protective role on cell survival and energy status. *Nupr1* also contributed to inhibiting protein synthesis and slowing the proliferation of

proximal tubular cells. Ischaemia-reperfusion injury causes p53-dependent G2/M arrest of renal tubular cells and subsequent renal fibrosis.[37] *Nupr1* is a positive regulator of p53.[38] Because we found a consistent increase in *Nupr1* levels in all the kidney injury models we tested (including ischaemia-reperfusion injury), *Nupr1* induction appears to be a generic response to any epithelial injury and is not cyclosporin-specific. Whether *Nupr1* induction is also protective in these other models remains to be tested. The mechanism by which the ATF4-NUPR1 pathway might influence evolution toward cell death or survival is outlined in Figure 9. Overall, *Nupr1* inhibits energetically costly processes (proliferation and protein synthesis) and preserves ATP cellular concentrations. ADP/ATP ratio is associated to apoptosis, and may be instrumental in this model. The molecular targets of *Nupr1* that lead to cell protection are still unknown, however. Further studies should therefore 1) investigate the precise mechanisms that regulate energy consumption, protein synthesis and proliferation downstream of *Nupr1*; 2) test strategies aimed at producing a time-limited expression of *Nupr1*-related pathways in acute kidney injury, and 3) determine whether *Nupr1* variants are involved in susceptibility to kidney injury in humans.

CONCISE METHODS

Animals. We used a model of *in vivo* renal toxicity by daily injections cyclosporin for 2 weeks.[39] JL Iovanna created the *Nupr1*$^{-/-}$ mouse strain.[38] Blood and kidneys were harvested under general anaesthesia. For creatinine clearance measurements, animals were placed overnight in metabolic cages for urine collection, and blood was collected from the retro-orbital sinus under isoflurane anesthesia. *Morphologic studies and laser microdissection*. Ki67 and TUNEL quantification were performed with the particle analysis function of ImageJ 1.45o software. For each sample, 200 cortical tubules were harvested by laser capture microdissection (Supplemental Figure 11). *RT-PCR and mRNA microarray*. Microdissected tubules were studied with the GeneChip Rat Genome 230 2.0 microarrays (Affymetrix). The

pathway analysis was performed with LrPath web-based software.[40] The quantitative RT-PCR expression results relative to the housekeeping gene were obtained by the ΔCp method. *In vitro studies*. Proximal epithelial cells were isolated from fresh kidneys of *Nupr1*$^{-/-}$ and WT mice.[41, 42] *Statistics*. Statistical analysis used JMP Pro 9.0.2 software. Data are presented by their median values and interquartile ranges, and a nonparametric Wilcoxon test was used to assess statistical significance, except where otherwise indicated. A *P*-value<5% was defined as significant. *Study approval.* Animals were handled in a licensed facility (approval number B-75-20-01) in compliance with French legislation and INSERM standards. Biopsies from renal-transplanted patients receiving cyclosporin treatment were used for NUPR1 immunohistochemistry. The biopsies were indicated for state-of-the-art routine care, and all patients provided written consent for use of the leftover material for research purposes. The study performed on human biospies was approved by our institutional review board.

FIGURE LEGENDS

Figure 1. *In vivo* renal tubular transcriptome analysis. **A.** Principal component analysis of the gene expression results. The 6 samples circled in red passed the quality check for further analysis. **B.** Volcano plot with -log *P*-value (t-test) along the y-axis and log fold-change along the x-axis. *Nupr1* is circled in red. **C.** mRNA expression by microarray (on a logarithmic scale ranging from 2 to 14) of representative markers for various segments of the nephron (*Megalin* and *Npt2a* for the proximal renal tubule, *Aqp2* for the collecting duct, *Nephrin* for the glomeruli, and *Cd31* for the endothelium) and known markers of renal tubular injury (*Kim1* and *Opn*). CsA-treated animals (CsA, n=3) were compared to the control group (CTL, n=3). Results were considered nonsignificant (NS) if the *P*-value (t-test) > 0.05. **D.** Summary of the logistic regression pathway analysis on KEGG pathways. The 5 pathways were enriched in the differential analysis between the CsA and the CTL group. Genes from the first 3 pathways were upregulated by cyclosporin, and genes from the last 2 pathways downregulated by it.

Figure 2. ATF4 protein expression 24h after CsA treatment assessed by immunohistochemical analysis (**A**) and by western blot (**B**) in renal tubules of mice, and at different time points (**C**). **A.** Tubules injured by CsA 100 mg/kg/d, for 14 days (CsA) overexpressed ATF4, compared with control kidneys (CTL). **B.** Photograph of the full western blots for ATF4 and GAPDH, with the protein ladder on the left (ATF4 and GAPDH corresponding to 50 and 40 kDa respectively), showing induction of ATF4 after 24 h exposure to 5 µg/mL of CsA in a primary cell culture of mouse proximal tubular cells (representative of 3 independent experiments). Extinction of ATF4 staining after transfection with an anti-ATF4 siRNA attests to the specificity of the anti-ATF4 antibody. **C.** Time course of ATF4 protein (n=2) with *Nupr1*, *Atf4, Chop* and *Bip* mRNA (n=4), after 1, 2, 3, 6 and 24 hours of CsA (1µg/mL) exposure, compared to vehicle.

Figure 3. **A, C, E**. Wild-type mice treated by cyclosporin 100 mg/kg/d for 14 days. **B, D, F**. *Nupr1*$^{-/-}$ animals treated by cyclosporin 100 mg/kg/d for 14 days. **A & B**. Masson's Trichrome. *Nupr1* deficiency exacerbated histological tubular lesions caused by cyclosporin: tubular vacuolisation and dilation. **C & D**. Ki67 immunohistochemistry. *Nupr1* deficiency was associated with increased tubular cell proliferation. **E & F**. TUNEL assay. *Nupr1* deficiency was associated with increased apoptosis. **G, H, I, J**. Quantification for tubular dilation (G), tubular vacuolisation (H) in wild type (n=12) and knock out (n=10) mice, Ki67 (I) and TUNEL (J) in wild type (n=6) and knock out (n=6) mice.

Figure 4. Assessment of protein synthesis using a pulse of L-homopropargylglycine (methionine analog) revealed by Alexa Fluor 488. **A.** Protein synthesis evaluation by immunofluorescence (in green) in wild type and *Nupr1-/-* proximal tubular cells incubated with 5 µg/mL CsA or vehicle for 24 hours. **B.** Protein synthesis evaluation by flow cytometry showing the percentage of cells in cell-cycle phase G1 undergoing protein synthesis, and the rate of protein synthesis (median fluorescence intensity) in these cells for wild type and *Nupr1-/-* cells treated for 24 hours with 5µg/mL cyclosporin or vehicle.

status.

Figure 5. Differential proliferation of WT and *Nupr1* knockout cells within 48 hours after seeding. **A**. Number of cells counted by flow cytometry in a well 48h after seeding 500 to 20000 of either KO or WT proximal tubular cells/well (96-wells plate). **B.** Photograph of the cells 48 hours after seeding 5000 of KO or WT proximal tubular cells per well. **C.** Real time monitoring of cell proliferation for 48 hours after seeding 1000 to 7000 cells/ well (96-wells plate) of either KO or WT proximal tubular cells, and monitoring of cell proliferation for 24 hours after seeding 5000 of KO or WT proximal tubular cells per well, followed by 24 hours incubation with 1µg/mL cyclosporine or vehicle.

Figure 6. **A.** Cell-cycle analysis using flow cytometry to assess DNA content by Propidium Iodide staining and DNA synthesis by BrdU incorporation, under normal conditions or under 1 µg/mL cyclosporin for 24 hours, according to *Nupr1* status (n=3). **B.** Rate of BrdU incorporation in BrdU positive cells assessed by flow cytometry, under normal conditions or under 1 µg/mL cyclosporin for 24 hours, according to *Nupr1* status (n=3). **C.** Apoptosis quantified by flow cytometry (prodidium iodide for necrosis and YO-PRO®-1 for apoptosis) *in vitro* under normal conditions or under 5 µg/mL cyclosporin for 24 hours, according to *Nupr1* status (n=5). **D.** ATP/ADP ratio *in vitro* under normal conditions (n=12) or under 1 µg/mL cyclosporin for 24 hours (n=6), according to *Nupr1*

Figure 7. Rescue of Nupr1-/- cells by transfection of a flag-Nupr1 transgene (n=3). A. Gating of single cells on DNA content using an area vs height dot-plot. B. Transfection resulted in only ~1% of flag-expressing cells. C. Transfection selective cell-cycle analysis, based on DNA content assessed by Hoechst staining.

Figure 8. A. Analysis of *Nupr1* expression (normalised on housekeeping gene *Hprt*) in human proximal tubular HK2 cells showed a dose-dependent induction of *Nupr1* mRNA by cyclosporin. **B, C, D, E.** Immunohistochemical analysis for NUPR1 in human renal allografts showing a normal biopsy 3 months after transplantation with no NUPR1 expression (C, E), and a biopsy with acute antibody-mediated rejection and chronic allograft dysfunction (D, F). C-D show NUPR1 expression, and E-F show the triple staining for nuclei (DAPI, blue), megalin (green), and NUPR1 (magenta) .

Figure 9. Schematic representation of the relations between kidney injury, the ATF4-NUPR1 pathway and epithelial fate.

SUPPORTING DOCUMENTS

Supplemental Figure 1. Dose-dependent cyclosporin nephrotoxicity at day 14 in C57bl6/J WT mice. **A.** Plasma urea in mice treated for 14 days with various doses of CsA (■ $P<0.05$; ◆ $P<0.005$ vs 0 mg/kg/d), and *Nupr1* relative quantification (normalised on the geometrical mean of the housekeeping genes *Rpl32* and *Gusb*) in the cortex of mice treated with various doses of CsA for 14 days. **B & C.** Masson's Trichrome of the kidneys of mice injected with vehicle, 60mg/kg/d or 100 mg/kg/d for 14 days (B: magnification x400, C: magnification x100). **D.** TUNEL assay of the kidneys of mice injected with vehicle, 60mg/kg/d or 100 mg/kg/d for 14 days (magnification x600). **E.** Ki67 staining of the kidneys of mice injected with vehicle, 60mg/kg/d or 100 mg/kg/d for 14 days (magnification x100).

Supplemental Figure 2. Time course of weight change (A), plasma urea (B), plasma creatinine (C), and creatinine clearance (D) in mice treated for 2 weeks by 100 mg/kg/day cyclosporine (CsA) or vehicle (CTL).

Supplemental Figure 3. Serial sections of control (A & B) and CsA-treated (C & D) mouse kidneys stained by immunohistochemistry for megalin (A & C) and CD44 (B & D).

Supplemental Figure 4. Additional markers of kidney injury in wild type (WT) or *Nupr1*-/- (KO) mice, with cyclosporine 100 mg/kg/j (CsA) or vehicle (CTL) for 14 days. A. Blood urea was significantly increased after CsA treatment, but did not differ significantly between genotypes (WTCTL: n=5, KOCTL, n=8, WTCsA: n=12, KOCsA: n=10). B. The level of mRNA from a kidney injury molecule 1 (KIM 1) after 14 days of CsA was significantly higher in *Nupr1*$^{-/-}$ than in WT mice (n=6 for each group).

Supplemental Figure 5. A. Serum cyclosporine trough levels after 2 weeks of 60 mg/kg SC cyclosporine daily were not different in wild type and *Nupr1-/-* mice (n=5). B. Expression of Il27 in the renal cortex of WT and *Nupr1* knockout mice (n=6). C and D. Mean aortic blood pressure and mean renal blood flow of knockout (KO) and wild-type (WT) mice treated by cyclosporin (CsA) or vehicle (CTL).

Supplemental Figure 6. Western blot of ATF4 normalized on GAPDH in wild-type (WT) and knock-out (KO) proximal tubular cells treated by cyclosporin (CsA) or vehicle (CTL).

Supplemental Figure 7. Gating strategy used for assessment of BrdU incorporation by flow cytometry in wild type and *Nupr1-/-* cells. BrdU-positive cells gated on the autofluorescence vs BrdU-FITC plot are shown in blue on the propidium iodide vs BrdU-FITC plot.

Supplemental Figure 8. ATP and ADP levels (arbitrary unit) in WT and *Nupr1* knockout cells after 24 hours exposure to 1 µg/mL cyclosporin (n=6) or its vehicle (n=12).

Supplemental Figure 9. Cell-cycle analysis of wild-type and *Nupr1-/-* proximal tubular cells after transfection with the *flag-Nupr1* transgene. Cells without expression of the transgene are shown in red, and cells expressing the transgene (identified with the anti-FLAG antibody) are shown in blue.

Supplemental Figure 10. Induction of *Nupr1* expression in various models of kidney injury. Moderate hypertension (HTA) was obtained through infusion of angiotensin 2 and low-dose of L-NAME, severe hypertension through infusion of angiotensin 2 plus high dose of L-NAME L-Name treatment. Ischaemia-reperfusion (IR) was performed by occluding the renal artery bilaterally for 35 minutes. Unilateral ureteral occlusion was performed by ureteral ligature for 10 days, and the contralateral kidney served as the control.

Supplemental Figure 11. A slide used for renal tubule microdissection. Note that the tubule contour was burned by the LASER, thus precluding extratubular contamination.

Dataset 1. Full results of the mRNA microarray analysis with expression data and comparison between the cyclosporin and control groups.

Supplemental Table 1. Results of the logistic regression pathway analysis with the details of the genes involved in enriched pathways.

Supplemental Table 2. Sequences of the primers used for RT-qPCR and details of the amplicon and spanned intron size.

MATERIAL AND METHODS

Animals. Animals were housed in standard conditions in the specific pathogen-free animal facility of Inserm UMR_S 1155, in ventilated boxes with a 12/12 photoperiod, at a 20-24°C temperature with a 55+/-10% humidity. Food and water were available *ad libitum*. We used a standard murine model of *in vivo* renal toxicity with daily subcutaneous injections of cyclosporin combined with a low-salt diet started one week before the first cyclosporin injection (Safe, 0.025% Na) [1]. For rat studies (5 rats per group), cyclosporin was injected at the dose of 15 mg/kg/day for 2 weeks, and rats injected with its vehicle (ricin oil) served as control. For mice studies, WT and *Nupr1*-deficient c57bl6/J mice were given 0, 30, 50, 60, 75 or 100 mg/kg/day subcutaneous cyclosporin for 2 weeks to assess the optimal nephrotoxic dose. Olive oil, the cyclosporin vehicle for mice, served as control. JL Iovanna created the *Nupr1*$^{-/-}$ mouse strain [2].

Renal haemodynamics experiments were performed on male *Nupr1*$^{-/-}$ and WT mice. Animal surgery and renal blood flow (RBF) measurements were performed after anaesthesia by pentobarbital sodium (50–60 mg/kg body weight intraperitoneal, Nembutal, Abbott, Chicago, IL); they were placed on a servo-controlled table kept at 37°C, with trachea cannulated to facilitate respiration. The left femoral artery was catheterised to measure arterial pressure, and a femoral venous catheter was used for infusion.

Arterial pressure was measured by a pressure transducer (Statham P23 DB), and RBF by a flowmeter (0.5-v probe, Transonic Systems TS420, Ithaca, NY). RBF values were controlled for zero offset, determined at the end of an experiment after cardiac arrest. Data were recorded, stored and analysed with DataTranslation analogue-to-digital converter and IOX software (EMKA Technologies, Paris France). Experiments were planned for a total of 8 *Nupr1*$^{-/-}$ and 8 WT mice (4 CsA-treated mice and 4 control each), but 1 mouse died in each of the WT CTL, WT CsA, and KO CsA groups during the catheterisation procedure, and 1 WT

CTL, 1 KO CTL and 2 KO CsA had early renal artery bifurcation that prevented measurement of renal blood flow.

Hypertension model: Hypertension was induced in c57bl6/J male mice by two protocols. In both protocols, animals were infused subcutaneously either with vehicle (NaCl 0.9%) (control animals) or angiotensin II (1µg/kg/min) (hypertensive animals) via osmotic minipumps during 28 days. NaCl 6g/L was added to drinking water for control and hypertensive animals during the first week. Hypertensive animals also received L-Nitro-Arginine-Methyl-Esther (L-NAME) in drinking water: 50mg/kg/j for 8 days and then 10mg/kg/j for 10 days during the first protocol, and 10mg/kg/j for 20 days during the second protocol. Animals developed severe hypertension (mean systolic blood pressure 159±21 mmHg) and severe renal lesions (arteriosclerosis, glomerulosclerosis, tubulointerstitial fibrosis) in the first protocol whereas hypertension (mean systolic blood pressure 146±21 mmHg) and renal lesions were moderate in the second protocol.

Ischaemia reperfusion injury: a bilateral posterior subcostal incision was made in male c57bl6/J mice, and the renal pedicle was dissected and occluded with a small vascular clamp. After 35 min, the clamp was removed. Animals were killed and the kidneys were harvested after 2 days. The surgery and the sacrifice were performed under general anesthesia (250 mg/kg body wt, Avertine, Sigma).

Ureteral unilateral obstruction: c57bl6/J male mice underwent left ureteral ligation under general anesthesia and were sacrificed ten days later. Right unobstructed kidney was used as control. Tubular dilatation, loss of brush border, interstitial inflammation and fibrosis were observed after ureteral obstruction. [3]

Animals were sacrificed at the end of each protocol by exsanguination under general anaesthesia (pentobarbital for rats and ketamine-xylazine for mice). Blood and kidneys were harvested.

Morphologic studies and laser microdissection. Masson's trichrome staining was used for morphology, and immunostainings were performed on paraffin tissue with specific antibodies for Ki67 (rabbit polyclonal, Abcam, #ab15580), Nupr1 (rabbit, developed by JL Iovanna), ATF4 (rabbit, clone D4B8, ref 11815S, Cell Signaling), megalin (sheep, [4]), CD44 (rat, clone IM7, Exbio). After target retrieval by heating the tissue in citrate ph6 solution, the slides were incubated with primary antibodies overnight at 4°C. Next, we incubated the slides 30 minutes with a secondary antibody (Histofine Simple Stain MAX PO, Nichirei Biosciences Inc and AEC+substrate-chromogen, Dako for immunohistochemistry and anti-goat Alexa Fluor488, Invitrogen for megalin immufluorescence). 1µg/mL DAPI (forimmunofluorescence) or Hematoxylin (for immunohistochemistry) was used to stain nuclei.

Apoptosis was studied by terminal deoxynucleotidyl transferase dUTP nick end labelling (TUNEL) assays. Ki67 and TUNEL quantification were performed with the particle analysis function of ImageJ 1.45o software after setting the threshold for the detection of nuclei on a control slide. For laser capture microdissection, 8-µm thick slices of kidney were placed on nuclease-free polyethylene naphthalate (PEN)-coated glass slides, stained with toluidine blue and fixed with ethanol. For each sample, 200 cortical tubules were carefully harvested to avoid contamination by extratubular material (Supplemental Figure 6).

RT-PCR and mRNA microarray. Microdissected tubules were immediately stored in lysis buffer for mRNA extraction with the RNeasy micro kit (Qiagen), and reverse transcription was performed with a WT-Ovation kit (Nugen). Target cDNA was marked and hybridised on GeneChip Rat Genome 230 2.0 microarrays (Affymetrix). After washing, images were acquired and computed into normalised intensities. The pathway analysis was performed with LrPath web-based software [5].

For RT-PCR, a piece of renal cortex was frozen in RNA Later (Qiagen, Courtaboeuf, France). RNA extraction was performed with TRIzol (Life Technologies, BRL, Gaithersburg, MD).

RNA quality was verified by measuring optical density ratios at 260 and 280 nm. We used Supercript II enzyme (Life Technologies BRL) for reverse transcription of 1 µg RNA into complementary DNA. Quantitative PCR was performed with a LightCycler 480 device (Roche Diagnostics, Meylan, France), SybrGreen (Fast Start DNA Master Sybr Green I; Roche Applied Science, Roche Diagnostic) and specific primers designed by Roche (Universal Probe Library, sequences detailed in Supplemental Table 2). RT-PCR was performed as follows: 95°C for 5 minutes, 45 cycles including 95°C for 15 seconds, 60°C for 15 seconds, 72°C for 15 seconds. The melting curve was used to assess the specificity of the PCR amplification. The quantitative RT-PCR expression results relative to the housekeeping gene were obtained by the ΔCp method

In vitro studies. Fresh kidneys from *Nupr1*$^{-/-}$ and WT mice were used for mechanical dissociation into a cellular suspension with the gentleMACS dissociator (Miltenyi Biotech). Proximal epithelial cells were isolated with anti-Prominin1 microbead-conjugated antibodies and LS magnetic columns (Miltenyi Biotech) [6]. Cells were grown on a modified DM medium [7]. ATP and ADP measurements were performed with the ApoSENSOR ADP/ATP ratio assay (Enzo Life Sciences), in accordance with the manufacturer's instructions.

Continuous proliferation assays were performed on 96 well plates using the xCELLigence device (Roche). Cells were seeded and a measurement was performed every 30 minutes for 24 hours, with additional measurements every 5 minutes for 8 hours after cyclosporin or vehicle administration.

For BrdU incorporation experiments we incubated the cells with 10µM BrdU (Roche 11-647-229-001) for 1 hour followed by a washout of one hour. BrdU was revealed using an anti-BrdU antibody (ebioscience 11-5071-42, clone BU20A) after treating the cells with ice-cold 70° ethanol followed by 2M HCl. Cells were resuspended for 15 minutes in a Propidium Iodide/ RNAseI solution (BD biosciences 550-825) before acquisition by flow cytometry.

Protein synthesis was assessed using the Click-iT® HPG Alexa Fluor® 488 Protein Synthesis Assay Kit (Molecular Probes, Life Technologies). Cells were incubated with L-homopropargylglycine (a methionin analog) for 30 minutes, and stained with Alexa Fluor 488 following the manufacturer's instructions. After acquiring the photographs, cells were trypsinized in the 96-well plates, and directly analyzed by flow cytometry.

Transfection with a pcDNA3 plasmid containing the *Flag-Nupr1* construct was performed using Attractene (#301005, Qiagen) following the manufacturer protocol for traditional transfection. Cells were trypsinized and permeabilized using the Cytofix/Cytoperm kit (#554714, Becton Dickinson) and following the manufacturer instructions, with an AlexaFluor 647 conjugated anti-FLAG antibody (#3916, Cell Signaling). Cell cycle analysis was performed after Hoechst 3342 was added.

Statistics. Statistical analysis used JMP Pro 9.0.2 software. Data are presented by their median values and interquartile ranges, and a nonparametric Wilcoxon test was used to assess statistical significance, except where otherwise indicated. A *P*-value<5% was defined as significant.

Study approval. Animals were handled in a licensed facility (approval number B-75-20-01) in compliance with French legislation and INSERM standards for laboratory animal care, including when necessary approval by our institutional review board (Comité National de Réflexion Ethique sur l'Experimentation animal, numéro 5) and the French Research Ministry (authorised project n° 00797.02, authorisation for animal experimentation n°A-75-1934). Biopsies from renal-transplanted patients receiving cyclosporin treatment were used for NUPR1 immunohistochemistry. The biopsies were indicated for state-of-the-art routine care, and all patients provided written consent for use of the leftover material for research purposes. The study on human renal biopsies was approved by our local Institutional Review Board.

MATERIAL AND METHODS

Animals. Animals were housed in standard conditions in the specific pathogen-free animal facility of Inserm UMR_S 1155, in ventilated boxes with a 12/12 photoperiod, at a 20-24°C temperature with a 55+/-10% humidity. Food and water were available *ad libitum*. We used a standard murine model of *in vivo* renal toxicity with daily subcutaneous injections of cyclosporin combined with a low-salt diet started one week before the first cyclosporin injection (Safe, 0.025% Na) [1]. For rat studies (5 rats per group), cyclosporin was injected at the dose of 15 mg/kg/day for 2 weeks, and rats injected with its vehicle (ricin oil) served as control. For mice studies, WT and *Nupr1*-deficient c57bl6/J mice were given 0, 30, 50, 60, 75 or 100 mg/kg/day subcutaneous cyclosporin for 2 weeks to assess the optimal nephrotoxic dose. Olive oil, the cyclosporin vehicle for mice, served as control. JL Iovanna created the *Nupr1*$^{-/-}$ mouse strain [2].

Renal haemodynamics experiments were performed on male *Nupr1*$^{-/-}$ and WT mice. Animal surgery and renal blood flow (RBF) measurements were performed after anaesthesia by pentobarbital sodium (50–60 mg/kg body weight intraperitoneal, Nembutal, Abbott, Chicago, IL); they were placed on a servo-controlled table kept at 37°C, with trachea cannulated to facilitate respiration. The left femoral artery was catheterised to measure arterial pressure, and a femoral venous catheter was used for infusion.

Arterial pressure was measured by a pressure transducer (Statham P23 DB), and RBF by a flowmeter (0.5-v probe, Transonic Systems TS420, Ithaca, NY). RBF values were controlled for zero offset, determined at the end of an experiment after cardiac arrest. Data were recorded, stored and analysed with DataTranslation analogue-to-digital converter and IOX software (EMKA Technologies, Paris France). Experiments were planned for a total of 8 *Nupr1*$^{-/-}$ and 8 WT mice (4 CsA-treated mice and 4 control each), but 1 mouse died in each of the WT CTL, WT CsA, and KO CsA groups during the catheterisation procedure, and 1 WT

CTL, 1 KO CTL and 2 KO CsA had early renal artery bifurcation that prevented measurement of renal blood flow.

Hypertension model: Hypertension was induced in c57bl6/J male mice by two protocols. In both protocols, animals were infused subcutaneously either with vehicle (NaCl 0.9%) (control animals) or angiotensin II (1µg/kg/min) (hypertensive animals) via osmotic minipumps during 28 days. NaCl 6g/L was added to drinking water for control and hypertensive animals during the first week. Hypertensive animals also received L-Nitro-Arginine-Methyl-Esther (L-NAME) in drinking water: 50mg/kg/j for 8 days and then 10mg/kg/j for 10 days during the first protocol, and 10mg/kg/j for 20 days during the second protocol. Animals developed severe hypertension (mean systolic blood pressure 159±21 mmHg) and severe renal lesions (arteriosclerosis, glomerulosclerosis, tubulointerstitial fibrosis) in the first protocol whereas hypertension (mean systolic blood pressure 146±21 mmHg) and renal lesions were moderate in the second protocol.

Ischaemia reperfusion injury: a bilateral posterior subcostal incision was made in male c57bl6/J mice, and the renal pedicle was dissected and occluded with a small vascular clamp. After 35 min, the clamp was removed. Animals were killed and the kidneys were harvested after 2 days. The surgery and the sacrifice were performed under general anesthesia (250 mg/kg body wt, Avertine, Sigma).

Ureteral unilateral obstruction: c57bl6/J male mice underwent left ureteral ligation under general anesthesia and were sacrificed ten days later. Right unobstructed kidney was used as control. Tubular dilatation, loss of brush border, interstitial inflammation and fibrosis were observed after ureteral obstruction. [3]

Animals were sacrificed at the end of each protocol by exsanguination under general anaesthesia (pentobarbital for rats and ketamine-xylazine for mice). Blood and kidneys were harvested.

Morphologic studies and laser microdissection. Masson's trichrome staining was used for morphology, and immunostainings were performed on paraffin tissue with specific antibodies for Ki67 (rabbit polyclonal, Abcam, #ab15580), Nupr1 (rabbit, developed by JL Iovanna), ATF4 (rabbit, clone D4B8, ref 11815S, Cell Signaling), megalin (sheep, [4]), CD44 (rat, clone IM7, Exbio). After target retrieval by heating the tissue in citrate ph6 solution, the slides were incubated with primary antibodies overnight at 4°C. Next, we incubated the slides 30 minutes with a secondary antibody (Histofine Simple Stain MAX PO, Nichirei Biosciences Inc and AEC+substrate-chromogen, Dako for immunohistochemistry and anti-goat Alexa Fluor488, Invitrogen for megalin immufluorescence). 1µg/mL DAPI (forimmunofluorescence) or Hematoxylin (for immunohistochemistry) was used to stain nuclei.

Apoptosis was studied by terminal deoxynucleotidyl transferase dUTP nick end labelling (TUNEL) assays. Ki67 and TUNEL quantification were performed with the particle analysis function of ImageJ 1.45o software after setting the threshold for the detection of nuclei on a control slide. For laser capture microdissection, 8-µm thick slices of kidney were placed on nuclease-free polyethylene naphthalate (PEN)-coated glass slides, stained with toluidine blue and fixed with ethanol. For each sample, 200 cortical tubules were carefully harvested to avoid contamination by extratubular material (Supplemental Figure 6).

RT-PCR and mRNA microarray. Microdissected tubules were immediately stored in lysis buffer for mRNA extraction with the RNeasy micro kit (Qiagen), and reverse transcription was performed with a WT-Ovation kit (Nugen). Target cDNA was marked and hybridised on GeneChip Rat Genome 230 2.0 microarrays (Affymetrix). After washing, images were acquired and computed into normalised intensities. The pathway analysis was performed with LrPath web-based software [5].

For RT-PCR, a piece of renal cortex was frozen in RNA Later (Qiagen, Courtaboeuf, France). RNA extraction was performed with TRIzol (Life Technologies, BRL, Gaithersburg, MD).

RNA quality was verified by measuring optical density ratios at 260 and 280 nm. We used Supercript II enzyme (Life Technologies BRL) for reverse transcription of 1 µg RNA into complementary DNA. Quantitative PCR was performed with a LightCycler 480 device (Roche Diagnostics, Meylan, France), SybrGreen (Fast Start DNA Master Sybr Green I; Roche Applied Science, Roche Diagnostic) and specific primers designed by Roche (Universal Probe Library, sequences detailed in Supplemental Table 2). RT-PCR was performed as follows: 95°C for 5 minutes, 45 cycles including 95°C for 15 seconds, 60°C for 15 seconds, 72°C for 15 seconds. The melting curve was used to assess the specificity of the PCR amplification. The quantitative RT-PCR expression results relative to the housekeeping gene were obtained by the ΔCp method

In vitro studies. Fresh kidneys from *Nupr1*$^{-/-}$ and WT mice were used for mechanical dissociation into a cellular suspension with the gentleMACS dissociator (Miltenyi Biotech). Proximal epithelial cells were isolated with anti-Prominin1 microbead-conjugated antibodies and LS magnetic columns (Miltenyi Biotech) [6]. Cells were grown on a modified DM medium [7]. ATP and ADP measurements were performed with the ApoSENSOR ADP/ATP ratio assay (Enzo Life Sciences), in accordance with the manufacturer's instructions.

Continuous proliferation assays were performed on 96 well plates using the xCELLigence device (Roche). Cells were seeded and a measurement was performed every 30 minutes for 24 hours, with additional measurements every 5 minutes for 8 hours after cyclosporin or vehicle administration.

For BrdU incorporation experiments we incubated the cells with 10µM BrdU (Roche 11-647-229-001) for 1 hour followed by a washout of one hour. BrdU was revealed using an anti-BrdU antibody (ebioscience 11-5071-42, clone BU20A) after treating the cells with ice-cold 70° ethanol followed by 2M HCl. Cells were resuspended for 15 minutes in a Propidium Iodide/ RNAseI solution (BD biosciences 550-825) before acquisition by flow cytometry.

Protein synthesis was assessed using the Click-iT® HPG Alexa Fluor® 488 Protein Synthesis Assay Kit (Molecular Probes, Life Technologies). Cells were incubated with L-homopropargylglycine (a methionin analog) for 30 minutes, and stained with Alexa Fluor 488 following the manufacturer's instructions. After acquiring the photographs, cells were trypsinized in the 96-well plates, and directly analyzed by flow cytometry.

Transfection with a pcDNA3 plasmid containing the *Flag-Nupr1* construct was performed using Attractene (#301005, Qiagen) following the manufacturer protocol for traditional transfection. Cells were trypsinized and permeabilized using the Cytofix/Cytoperm kit (#554714, Becton Dickinson) and following the manufacturer instructions, with an AlexaFluor 647 conjugated anti-FLAG antibody (#3916, Cell Signaling). Cell cycle analysis was performed after Hoechst 3342 was added.

Statistics. Statistical analysis used JMP Pro 9.0.2 software. Data are presented by their median values and interquartile ranges, and a nonparametric Wilcoxon test was used to assess statistical significance, except where otherwise indicated. A *P*-value<5% was defined as significant.

Study approval. Animals were handled in a licensed facility (approval number B-75-20-01) in compliance with French legislation and INSERM standards for laboratory animal care, including when necessary approval by our institutional review board (Comité National de Réflexion Ethique sur l'Experimentation animal, numéro 5) and the French Research Ministry (authorised project n° 00797.02, authorisation for animal experimentation n°A-75-1934). Biopsies from renal-transplanted patients receiving cyclosporin treatment were used for NUPR1 immunohistochemistry. The biopsies were indicated for state-of-the-art routine care, and all patients provided written consent for use of the leftover material for research purposes. The study on human renal biopsies was approved by our local Institutional Review Board.
