28 **Abstract**

29

30 The recent increase in sea surface temperature and ocean acidification raises major concerns
31 about the evolution of the coral calcification rate. Digitized x-radiographs have been used for
32 coral skeleton density measurements since the 1980s. The main limitation of coral
33 densitometry from digitized x-radiographs is the x-ray intensity heterogeneity due to spherical
34 spreading (inverse square law) and heel effect. Until now, extra x-ray images or aluminum
35 standards have been used to correct x-radiographs. However, such corrective methods may be
36 constraining when working with a high number of coral samples. Here, we present an
37 inexpensive, straightforward, and accurate Digital Detrending (DD) method to correct the
38 heterogeneities of the x-ray irradiation that affect x-ray images. The x-radiograph is corrected
39 against the irradiation imprint recorded by its own background using a Kriging interpolation
40 method, thus allowing reliable optical density measurements directly on the corrected x-ray
41 image. This Digital Detrending (DD) method was validated using skeletal bulk density
42 measurements and Computerized Tomography (CT). Coral densitometry using DD corrected
43 x-radiographs does not require the destruction of the coral sample and provides high-
44 resolution measurements. Since DD does not require extra aluminum standards to correct x-
45 radiographs, this method optimizes the working space available on the x-ray image.
46 Moreover, it corrects the entire x-radiograph, thus larger samples or numerous samples can be
47 x-rayed at the same time.

57

58 **Introduction**

59

60 Recent changes evidenced in global Sea Surface Temperature (SST) and oceans' pH, raise
61 major concerns about the future of coral reefs (Kleypas, 1999; IPCC, 2007, 2007; Pandolfi et
62 al., 2011). A major consequence of ocean pH decrease is the diminution of the aragonite
63 saturation state (Ω_{arag}). A compilation of data documenting calcification response to the Ω_{arag}
64 decrease among individual coral species, coral mesocosms and in situ reef communities,
65 showed that this response was consistently negative (Pandolfi et al., 2011). Since the early
66 1990's an unprecedented declining trend of the coral calcification rate (product of the annual
67 extension rate and the coral skeleton density) has been observed in Great Barrier Reef records,
68 most probably due to the recent increase in SST and to ocean acidification (Cooper et al.,
69 2008; De'ath et al., 2009). Conversely, coral response to combined ocean warming and pH
70 decrease appears highly variable and often non-linear. Moreover, coral response is also
71 greatly influenced by other factors such as nutrients, pollutants or salinity so that projecting
72 the future of coral reefs in a global warming and ocean acidification context is still uncertain
73 (Pandolfi et al., 2011). As stated by the IPCC report (2007) "acidification is an emerging
74 issue with potential for major impacts in coastal areas, but there is little understanding of the
75 details. It is an urgent topic for further research, especially programmes of observation and
76 measurement". Documenting the long term trends in coral calcification is crucial in
77 understanding the mechanisms and implications of ocean acidification on coral reefs, in order
78 to predict coral reef future.

79 Coral calcification rate (CR) is calculated by $\mathbf{CR} = \mathbf{ER} \times \mathbf{d}$, where (**ER**) is the annual
80 extension rate and (**d**) is the coral skeleton density. Whereas extension rate can be directly
81 measured from the banding pattern revealed by x-radiography, many methods have been

82 developed since the 1970s to measure skeletal density. Direct measurements have been
83 performed based on mercury displacement (Dustan, 1975), water displacement (Hughes,
84 1987) and coral pore volume calculation (Carricart-Ganivet et al., 2000). Although these
85 methods provide reliable measurements, they are time consuming, imply the destruction of
86 the sample and provide low measurement resolution (generally performed by sampling annual
87 growth increments). Methods that do not require the destruction of the coral sample, such as
88 gamma densitometry (Chalker and Barnes, 1990) or medical x-ray Computerized
89 Tomography (CT) (Bosscher, 1993) are quick and provide higher resolutions (less than one
90 millimeter, i.e., monthly resolution or higher). However, these methods rely on specialized
91 and expensive equipment, not always easily accessible. Alternative methods for coral skeleton
92 density measurement are based on digitized x-radiographs (Chalker et al., 1985; Helmle et al.,
93 2000; Carricart-Ganivet and Barnes, 2007). Optical densities (OD)¹ of x-radiographs are
94 measured on film or on digital images and converted into density values using OD reference
95 standards (e.g., *Tridacna maxima* shells and/or aluminum wedges).

96 An important drawback is that x-radiographic instruments do not provide uniform irradiation
97 of the entire area covered by the x-ray film and may therefore result in misleading density
98 measurements. Two reasons account for such irradiation heterogeneities: the heel effect which
99 is defined by an irradiation gradient along the anode-cathode axis and the inverse square law
100 which states that the irradiation is inversely proportional to the square of the distance from the
101 x-ray source (Meredith and Massey, 1971; Chalker et al., 1985; Helmle et al., 2000; Carricart-
102 Ganivet and Barnes, 2007). The irradiation gradient caused by the heel effect may lead to
103 biases in density measurements up to 26% (Chalker et al., 1985), which is similar to the
104 seasonal density variations that are reported for massive corals *Montastrea annularis* (20% -
105 Carricart-Ganivet and Barnes, 2007), *Porites* sp. (15% - this study) and *Siderastrea siderea*

1 In the following study the Optical Density (OD) refers to the grey level from 0 to 255 corresponding to the 8 bits coding of the digital images.

106 (30% - this study). Several alternative methods have been proposed to overcome such
107 miscalculations. For example, Helmle et al. (2002) performed paired x-radiographs (using the
108 same settings) of a coral sample and an aluminum plate. Therefore, it was possible to correct
109 the coral sample image from the irradiation heterogeneities recorded by the aluminum plate's
110 x-radiograph. However, considering that each x-radiograph has to be taken twice, this
111 technique becomes expensive and time-consuming when a high number of samples have to be
112 analyzed. Carricart-Ganivet and Barnes (2007) proposed a simple way for correcting the heel
113 effect. The correction is based on the measurement of OD variations on an aluminum bar
114 located beside the coral sample along the anode-cathode axis. The heel effect-related
115 distortions are then measured, and extrapolated over coral samples. The method provides a
116 reliable one-dimensional correction along the anode-cathode axis. Unfortunately, the
117 extrapolation of this correction to the whole x-radiograph image may only be applied upon
118 particular settings (x-ray source to film distance and film dimension).

119 In the present study, we introduce a Digital Detrending (DD) method which corrects the
120 heterogeneously irradiated x-radiographs. This method is inexpensive, straightforward and
121 accurate. The DD method uses the x-ray irradiation imprint, recorded by the x-radiograph's
122 background, to reconstruct a full image of the irradiation pattern. The x-radiograph's
123 background is defined here as the image area without any objects or graphical information
124 such as letters or numbers. The resulting modeled image is then subtracted from the original
125 x-ray image, therefore enabling reliable optical density measurements from the corrected x-
126 ray image. This method provides a correction of x-ray irradiation heterogeneities on the whole
127 x-radiograph, which means a two-dimensional correction. The Digital Detrending (DD)
128 method was used for densitometry measurements on samples of widely studied massive corals
129 *Porites* sp. and *S. siderea* (Guzman and Tudhope, 1998; De'ath et al., 2009; Lough and
130 Cooper, 2011).

131 **Materials and Methods**

132

133 ***Computed x-radiography***

134

135 Experiments were performed using a medical Computed Radiography (CR) device. CR
136 produces digitized images obtained directly from an imaging plate (IP) instead of a
137 conventional photo sensitive film. IP is placed beneath coral slabs before being irradiated
138 (Fig. 1a). The final result is an 8 bits digitized image (pixel values comprised between 0 and
139 255). Such an image can be used for Optical Density (OD) measurements and be easily
140 modified with conventional image-processing software. CR is affected by heterogeneous x-
141 ray irradiation just like conventional radiography.

142 The CR device was a SUPER CONTACT® x-ray device (General Electric Company). X-
143 radiographs were acquired with FUJI® imaging plates made of photosensitive phosphorus.
144 Digitized images were then obtained using an IP reader (FUJI® FCR 5000). The resolution of
145 this device is lower than conventional x-radiography.

146

147 ***X-ray irradiation heterogeneities***

148

149 Heel effect - The heel effect is responsible for the irradiation intensity gradient along the
150 anode-cathode axis: the electrons emitted from the cathode interact with the anode resulting in
151 a high exposure at the cathode side of the IP and a decrease toward the anode side (Fig. 1b).

152 Inverse square law - The inverse square law models the three-dimensional spherical spreading
153 of the x-ray beam: irradiation intensity is attenuated by a factor proportional to the inverse of
154 the squared distance from the x-ray source to the IP surface. As IP are generally centered

155 beneath the x-ray source, the irradiation pattern shows over-exposed area at the center of the
156 image, decreasing toward the edges (Fig. 1b). The influence of spherical spreading on the
157 irradiation pattern gets lower with increasing source-subject distance.

158

159 The inverse square law specifies that the ratio of x-ray intensity on the IP (I_1) to intensity on
160 the subject surface (I_2) is:

$$161 \quad \frac{I_1}{I_2} = \frac{(S_p - s)^2}{(S_p)^2} \quad (1)$$

162 Where S_p = source to IP distance and s = sample thickness.

163

164 ***Computed Tomography***

165

166 Computed Tomography (CT), with its high-contrast resolution, allows accurate and reliable
167 density measurements, as this method is not influenced by the x-ray beam distortion
168 phenomena that usually affect computed radiography. A CT-scan was used to compare
169 density profiles measured on DD corrected images to the density profile of the CT scan. The
170 Computerized Tomography device used was a Phillips Brilliance 40®. CT density values are
171 expressed as Hounsfield units.

172

173 ***Reference materials***

174

175 We used two massive corals slabs as reference samples. Reference slab R_s was cut off a core
176 drilled in 2008 from a living colony of the reef-building species *S. siderea* at Cahuita reef
177 (9°44'N - 82°48'W), Limón, Costa Rica. R_s size was 280 x 70 mm; slab thickness (s) was 5

178 mm. Reference slab R_p was cut off from a living colony of the reef-building species *Porites*
179 sp. at the Fausse Passe de Uitoé reef (22°17'S - 166°10'E), New-Caledonia, France, in 2010.
180 This coral was collected alive and transferred into an aquarium in 2008. R_p size was 150 x
181 150 mm and the slab thickness (s) was 10 mm. For coral density measurements, a reference
182 transect for both slabs was set along the maximum growth axis, perpendicular to the growth
183 increments. For R_s , the reference transect tr_s was 87 mm long and encompassed 15 couplets
184 of high and low density bands; for R_p , the reference transect tr_p was 130 mm long and
185 encompassed 13 couplets of high and low density bands. In order to avoid as much as possible
186 intra-corallite density variations, the width of the density transects was 10 mm to include
187 approximately three *S. siderea* corallites (polyps mean diameter ~ 3 mm) and ten *Porites* sp.
188 corallites (polyps mean diameter ~ 1 mm).

189

190 ***Density scaling***

191

192 Density scaling is based on two, two-sided wedges (d_{clam} – Fig. 1c) cut from the internal layer
193 of a giant clam's shell *Tridacna squamosa*. One wedge is 17.4 mm high and 54.2 mm long
194 with slopes of 26.6° and 41.2°. The second wedge is 15.9 mm high and 71.8 mm long with
195 slopes of 43.4° and 16.0°. The bulk densities of the wedges were obtained by weighting with
196 a hydrostatic balance.

197 Care should be given when cutting a wedge into a giant clams' shell as it is composed of three
198 distinct aragonitic layers (internal layer, external layer and hinge layer) which present their
199 distinct density and crystallographic structure (N. Duprey, unpublished data). To avoid any
200 measurement bias, wedges must be cut into either external or internal shell layer. X-
201 radiographs revealed that the density of the whole shell's internal layer (d_{shell}) was
202 homogeneous.

203 To ensure the consistency of the density scaling, another scaling standard (d_{powder}) was added
204 on some x-radiographs for comparison purposes. Standard d_{powder} is composed of 14 plastic
205 cubes filled with Porites sp. coral aragonite powder (grain size $< 200 \mu\text{m}$). Each cube was
206 filled with a carefully weighted amount of powder to obtain a density scale from 0 to 3 for an
207 equivalent sample thickness of 12 mm.

208 Both plastic cubes filled with coral powder and wedges have a similar range of density values.
209 However, wedges were favored for their small sizes because this optimizes the space
210 available on the x-radiograph, so that more coral samples can be x-rayed at the same time.

211

212 ***X-radiographs***

213

214 All the x-radiographs and their characteristics are listed in table 1. For this study, we used
215 eight x-radiographs made with the CR device previously described. The main purpose of
216 these x-radiographs was to test the reliability of the Digital Detrending method depending on
217 the distance S_p and samples orientation along the anode-cathode axis. Therefore, coral
218 reference samples were placed along three directions with regard to the anode-cathode axis:
219 perpendicular, parallel and diagonally. Selected distances (S_p) were 130cm, 100cm and 80cm.
220 X-radiographs were acquired over a two-year period, providing the opportunity to test the DD
221 method against a potential machine drift over time.

222 Merely considering the inverse square law and the IP size (355 x 428 mm), the minimum
223 exposures at image edges would be 11.8%, 8.1% and 5.0% less than the exposures at the
224 center for $S_p=80\text{cm}$, $S_p=100\text{cm}$ and $S_p=130\text{cm}$, respectively.

225 X-radiograph C2 was used to test the density calibration of the two density standards (d_{powder}
226 and d_{clam}). For that purpose we used 13 Porites sp. cubes ($\sim 2\text{cm}^3$) which bulk densities were

227 determined by weighting with a hydrostatic balance. Coral cubes density ranged from 1.21 to
228 1.39 g.cm⁻³.

229

230 ***Digital Detrending procedure***

231

232 The first stage of the digital detrending (DD) process is the background area selection. This
233 area is used as a recorder of the irradiation pattern. The background area selection aims to
234 remove all saturated margins, all pixels corresponding to samples and optical density scale or
235 information, from the original x-radiograph (Fig. 2a). This background extraction is made
236 using the magic stick tool of the image processing software GIMP[®] (or equivalent). This step
237 leaves empty areas corresponding to objects' locations (Fig. 2b). Missing OD values are
238 interpolated using a Kriging interpolation from the dacefit MATLAB[®] toolbox (Lophaven et
239 al., 2002). The result is a complete image of OD variations (Fig. 2c) following the overall
240 pattern presented by the original background area. The corrected image is obtained by
241 subtracting the modeled background to the original image (Fig. 2d).

242 The DD method initially supposes that the x-ray intensity at the IP surface is similar to the x-
243 ray intensity at the sample surface. However, x-ray source to sample surface distance (S_s) is
244 smaller than x-ray source to IP surface distance (S_p). Considering equation (1), it can be
245 stated that the spherical spreading causes the x-ray intensity to be higher at the sample surface
246 than at the IP surface. This may generate a small bias in measurement, thereafter referred as
247 thickness bias, leading to a slightly overestimated density. This bias can be reduced by
248 decreasing the sample thickness and corrected during the DD process by dividing
249 corresponding background values with the ratio I_1 / I_2 .

250 X-ray attenuation in air may also account for the difference between x-ray intensities at
251 sample and IP surfaces. Coral densitometry studies are usually performed on samples with

252 thickness less than 10 mm. According to the air mass attenuation coefficient table from the
253 National Institute of Standards and Technology, x-ray attenuation for a 10 mm air layer is
254 negligible (Table 2).

255

256 **Digital Detrending evaluation**

257

258 In order to optimize the DD procedure we had to test first if the x-ray irradiation imprint on
259 the IP remains identical while maintaining the x-ray source settings and the Sp distance
260 constant (α). If this last assumption is true, then a standard correction could be used within a
261 group of x-radiographs made with the same settings. Therefore, the DD procedure would be
262 simplified and faster. If not, each x-radiograph should be corrected with the irradiation record
263 of its own background. By taking pair-wise images, α was tested using the mean relative
264 difference of OD ($\Delta OD_{(i,j)}$).

265 The relative difference of OD ($\delta OD_{(i,j,k)}$) at point k for images i and j is defined as:

$$266 \quad \delta OD_{i,j,k} = \frac{|(OD_i(x_{(k)}, y_{(k)})) - OD_j(x_{(k)}, y_{(k)})|}{OD_i(x_{(k)}, y_{(k)})} \quad (2)$$

267 Where $OD_i(x_{(k)}, y_{(k)})$ is the OD value at image coordinates $(x_{(k)}, y_{(k)})$ for image i and $OD_j(x_{(k)}, y_{(k)})$
268 is the OD value at image coordinates $(x_{(k)}, y_{(k)})$ for image j.

269 The mean relative difference of OD ($\Delta OD_{(i,j)}$) for images i and j is:

$$270 \quad \Delta OD_{i,j} = \frac{1}{n} \cdot \sum_{k=1}^n \delta OD_{i,j,k} \quad (3)$$

271 Where n is the number of pixels coordinates shared by images i and j backgrounds.

272 Considering the causes of the x-ray irradiation heterogeneities, the reliability of the Digital
273 Detrending process had to be tested through two other assumptions.

274 The DD method corrects and preserves the density information of the sample independently
275 of:

276 (β) - the sample orientation along the anode-cathode axis

277 (γ) - the distance S_p

278 The density information of the coral samples refers to the density variability (qualitative
279 information) and to the density value (quantitative information). β was tested by measuring
280 the coral density profiles (tr_s and tr_p) on samples set perpendicularly, parallel and diagonally
281 to the anode/cathode axis, while the other settings remained unchanged. Intra-group A density
282 transects comparisons evaluated the ability of the DD method to correct the irradiation
283 heterogeneities mainly caused by the heel effect (independently of the samples orientation
284 along the anode-cathode axis). Intra-group B density transects comparisons evaluated the
285 correction of both the heel effect and the inverse square law heterogeneities (independently of
286 the samples orientation along the anode-cathode axis). γ was tested by inter-groups (A and B)
287 comparisons. The comparison of inter-groups (A, B and C) was used to assess the ability of
288 the DD method to cope with a potential machine drift over time. Finally, to ensure that the
289 DD method yields the same density variations as other density measurement techniques, the
290 density measurements made on a DD corrected image were compared to Computed
291 Tomography scanning measurements.

292 To test the previous assumptions, density values were measured along tr_s and tr_p for each x-
293 radiograph. The correlation between the density profiles was tested using the regression
294 coefficient R^2 . Furthermore, relative standard deviations (rsd) were calculated at each point
295 along transects of the compared x-radiographs and averaged in order to compile the results.
296 These mean Relative Standard Deviation (RSD) values were used to evaluate the precision
297 (reproducibility) of density measurements.

298 The mean Relative Standard Deviation (RSD) for compared transects is defined as:

299
$$\text{RSD} = \frac{1}{p} \cdot \sum_{i=1}^p \text{rsd}_i \quad (4)$$

300 Where p is the number of points along the compared transects [p(tr_s)=439 and p(tr_p)=666] and
301 rsd_i represents the relative standard deviation of the density at point i.

302

303 ***Density calibration***

304

305 OD values were converted into densities using the two, two-sided wedges cut from the
306 internal layer of a giant clam's shell *Tridacna squamosa*. The OD values on DD corrected x-
307 radiographs were measured along the two sides of both wedges using the ImageJ[®] software.
308 As giant clam shell also contains organic matter, which influences bulk density, wedges
309 thicknesses had to be corrected in order to obtain equivalent thicknesses, corresponding to
310 wedges made of pure aragonite. Thereafter, a wedge's equivalent thickness was defined as
311 T_{w100}.

312 The equivalent thickness scaling at each point along a wedge was calculated by:

313
$$T_{w100} = \frac{T_x \cdot d_{\text{shell}}}{d_{\text{arag}}} \quad (5)$$

314 Where T_x = measures wedge thickness, d_{shell} = shell wedge density (g.cm⁻³) and d_{arag} = density
315 of pure aragonite (2.930 g.cm⁻³).

316

317

318 OD values were then paired with corresponding equivalent thicknesses (T_{W100}) calculated
319 along the wedges. Paired OD and T_{W100} values from the two wedges were pooled and fitted
320 by a quadratic polynomial function:

$$321 \quad OD = a \cdot T_{w100}^2 + b \cdot T_{w100} + c \quad (6)$$

322 Where a, b and c constants are the coefficients determined by the polynomial fitting for the
323 studied x-radiograph.

324 Equation (6) obtained from the wedges' data was then reversely used to convert OD values of
325 coral samples into pure aragonite equivalent thicknesses (T_{S100}). Subsequently, coral sample
326 density values (d) were obtained from T_{S100} :

$$327 \quad d = \frac{T_{s100}}{T_s} \cdot d_{arag} \quad (7)$$

328 Where d = coral sample density ($\text{g}\cdot\text{cm}^{-3}$), T_{S100} = pure aragonite equivalent thickness for coral
329 sample, T_s = measured coral sample thickness; d_{arag} = density of pure aragonite ($2.930 \text{ g}\cdot\text{cm}^{-3}$).

330

331 ***Calibration's validation***

332

333 In order to validate our density calibration using *T. squamosa* wedges, OD measurements
334 were performed on coral cubes and plastic cubes filled with coral powder on the detrended x-
335 radiograph C1. OD values were converted into densities using previous equations (5) to (7).
336 These values were regressed against bulk density measurements performed on the same coral
337 and plastic cubes standards.

338

339

340 The relative error (re_i) of x-radiograph density measurements was calculated for each coral
341 cube:

$$342 \quad re_i = 100 \cdot \frac{|d_{\text{calc.}(i)} - d_{\text{bulk}(i)}|}{d_{\text{bulk}(i)}} \quad (8)$$

343 Where $d_{\text{calc.}(i)}$ is the density of coral cube i calculated from OD after digital detrending ($\text{g}\cdot\text{cm}^{-2}$)
344 3) and $d_{\text{bulk}(i)}$ is the bulk density ($\text{g}\cdot\text{cm}^{-3}$) of coral cube i .

345 The mean Relative Error (RE) of x-radiograph density measurements was evaluated by
346 averaging the relative errors (re_i) of coral cubes:

$$347 \quad RE = \frac{1}{n} \cdot \sum_{i=1}^n re_i \quad (9)$$

348 Where $n=14$ is the number of coral cubes (Porites sp.).

349

350 RESULTS

351

352 *Reproducibility of the irradiation imprint (α)*

353

354 The background area of the eight x-radiographs viewed in false colors show a strong OD
355 gradient along the anode-cathode axis, with low OD at the anode side increasing toward the
356 cathode side. This pattern is characteristic of the heel effect (Fig. 1a). A concentric OD
357 pattern, characteristic of the spherical spreading, is noticeable on some images. As expected,
358 x-radiographs with high distance Sp (groups A) present a less marked concentric pattern than
359 x-radiographs with low distance Sp (group B). OD mean relative difference (ΔOD) of x-
360 radiographs backgrounds ranges from 8% up to 290% (Table 3). Intra-group and inter-group
361 comparison lead to similar ΔOD : most x-radiographs present highly variable background OD
362 values: assumption α is thus not valid within our experimental settings.

363 ***Influence of the sample orientation along the anode-cathode axis (β) and of the Sp distance (γ)***

364

365 Density profiles measured on corrected x-radiographs of groups A and B are well correlated
366 (Table 4). Inter-group and intra-group correlation coefficients values (R^2) are significant and
367 have a similar range from 0.90 to 1.00 ($p < 0.001$).

368 Inter-group and intra-group mean relative standard deviation (RSD) of densities measured on
369 uncorrected images range from 10.1 to 16.0% (Table 5). Density profiles measured on
370 corrected images show a RSD reduced by a factor of 2 to 3. No differences are noticed
371 between the inter-group RSD and intra-group RSD, which are both around 4-5%.

372 The variations and the precision of density measurements from the corrected images show no
373 difference regarding the sample orientation along the anode-cathode axis (β) or the Sp
374 distance (γ). Assumptions β and γ are thus validated within our experimental settings.

375

376 ***Density measurement precision on DD corrected images***

377

378 RSD calculated over all uncorrected x-radiographs (groups A, B and C, 14 transects = 7 x tr_s
379 and 7 x tr_p) reaches 16.1% (Table 5). RSD calculated over all DD corrected x-radiographs is
380 6.8%. These values include measurements made on x-radiographs of two coral samples of
381 different genus, set on three different ways along the anode-cathode axis, with three different
382 distances (Sp), made across a two-year period.

383

384 ***Density variations***

385

386 The tr_s and tr_p density profiles, measured on uncorrected images, shown as examples on figure
387 3, present seasonal density variations comprised around 30 and 15% respectively. Profile tr_s

388 measured on the uncorrected image presents an increasing trend with a maximum density
389 difference reaching 50%. The mean profile tr_s from DD corrected images does not present any
390 remarkable trend. This mean profile tr_s shows density variations identical to the CT scan
391 density profile variations (Fig. 3a). This correlation is a robust result as each of the seven
392 density profiles tr_s , measured on corrected x-radiographs, are significantly correlated with the
393 density profile made on the CT scan ($0.89 < R^2 < 0.96$; $p < 0.001$; Table 6). The DD method
394 thus eliminates the density trend caused by the x-ray heterogeneities. Conversely, the
395 magnitude of the seasonal density variations is not affected by the DD correction.

396 Profile tr_p from the uncorrected image (Fig. 3b) displays a density drop that matches with the
397 transfer of sample R_p from the reef to the aquarium. This profile also displays a parabolic
398 trend with a maximum density difference reaching 50%. The DD method removes the
399 parabolic trend of the profile tr_p , and highlights a linear declining trend with density
400 difference reaching 40%. The density drop (sample R_p transfer) is not affected by the DD
401 correction.

402

403 ***Density Calibration***

404

405 The four sides of the two, two-sided *T. squamosa* wedges (Fig. 1c) returned identical OD
406 versus T_{w100} profiles ($R^2=0.9998$, $p < 0.001$, Fig. 4). Density values, calculated from corrected
407 x-radiograph C2, are regressed against the bulk density values (coral cubes and plastic cubes
408 filled with coral powder – Fig. 5). This regression presents a significant correlation coefficient
409 ($R^2=0.99$; $p < 0.001$; $n=27$). Comparison between bulk densities of the 14 *Porites* sp. coral
410 cubes and the calculated density values show that the mean relative error (RE – equation 9) is
411 3.32%.

412

413 **DISCUSSION**

414

415 Computed x-radiographs commonly show an uneven exposure due to both the heel effect and
416 the spherical spreading. Such irradiation heterogeneities may lead to variations in coral
417 density up to 50% (Fig. 3). These density variations exceed the seasonal variations commonly
418 observed in massive coral: 30% for *Siderastrea siderea*, 15% for *Porites* sp. and about 20%
419 for *Montastrea annularis* (Carricart-Ganivet and Barnes, 2007). These variations in density
420 may lead to biased calcification rate calculation and thus to wrong environmental
421 interpretations.

422 The Digital Detrending method, presented here, aimed to correct the irradiation
423 heterogeneities that affect conventional and computed x-radiography. X-radiographs were
424 corrected against the irradiation pattern recorded by the background of the image. The first
425 step of this study was to test if the x-ray irradiation imprint on the Imaging Plates (IP) remains
426 identical while maintaining the x-ray source settings and the Sp distance constant. Our results
427 showed that the x-ray irradiation imprint recorded by the IP was highly variable, even within
428 constant x-ray source settings and Sp distance. X-ray irradiation records must be considered
429 as unique and thus cannot be transposed to another x-radiograph, even within constant
430 settings. These results are in accordance with previous studies (Chalker et al., 1985; Carricart-
431 Ganivet and Barnes, 2007). The x-ray irradiation records may be affected by several factors
432 including the x-ray device stability, the x-ray tube aging and also the recording abilities of the
433 IP or film sensitiveness (Carricart-Ganivet and Barnes, 2007).

434 Density profiles from DD corrected x-radiographs were highly correlated to the density
435 profile measured on the Computed Tomography scan. These R² correlation values were not
436 affected by the orientation of the sample along the anode-cathode axis and the distance from
437 the x-ray source (Table 6). The DD method was thus able to correct x-radiographs of coral

438 samples, showing strong irradiation heterogeneities; independently of the sample orientation
439 along the anode-cathode axis and the distance from the x-ray source. Furthermore, this study
440 revealed that the coral intrinsic density variations (e.g., seasonal density variations or punctual
441 events) contained by the x-radiograph are preserved during the DD process (Fig. 3).

442 The mean relative error on density measurements of 14 coral cubes of *Porites* sp., using giant
443 clam *Tridacna squamosa* wedges as density standard (equation 9), was 3.32%. Causes of such
444 an error may be related to the IP sensitiveness (i.e., signal to noise ratio) and to the chemical
445 composition differences between giant clams shell and coral skeleton that could induce a bias
446 up to two percent in density measurements (Chalker et al., 1985). Carbonate structure
447 differences between coral slabs and shell wedges may also contribute to this error, potentially
448 generating diffusion and/or diffraction of the incident x-ray.

449 Enhancing the number of density measurements from 14 up to 7735 measured points (439x7
450 tr_s values and 666x7 tr_p values), the overall precision of the coral densitometry from DD
451 corrected x-radiographs reaches 6.8% (Table 5 and Fig. 3). It is important to notice that this
452 value includes the error intrinsic to-x-radiography device (noise of the recorded x-ray signal
453 and potential machine drift over time), the error related to the DD correction itself and the
454 error of the density calibration process. This value is noteworthy compared to the biases in
455 density measurements, caused by uncorrected irradiation heterogeneities that reach up to 50%.
456 In addition, the overall error on density measurement is below the range of the seasonal
457 density variations reported previously for massive coral skeleton.

458 The efficiency of our DD method relies on the x-ray irradiation pattern recorded by the
459 background. As a result, it is necessary to optimize the background area all over the x-
460 radiograph: samples must be scattered all over the IP with spacing of a few centimeters in
461 between and from the plate edges. We recommend to space x-rayed objects by more than one
462 centimeter between each and to keep a two centimeter margin from the edges. Consequently,

463 larger samples or numerous samples can be x-rayed at the same time and compared on the
464 same image as shown on x-radiograph C1 (Fig. 2). The DD method is straightforward, as it
465 does not rely on specific radiography device settings and does not need any prior assumption
466 on the causes of x-ray beam heterogeneities. DD method saves time as it does not require
467 extra x-radiographs to correct the irradiation heterogeneities. Our detrending method could
468 also be applied onto digitized conventional x-radiographs. The DD method applied to such x-
469 radiographs would provide the opportunity to perform qualitative density measurements on x-
470 radiographs from previous studies. Quantitative density measurements would be even possible
471 for x-radiographs acquired with a density scale.

472 The Digital Detrending method is a powerful tool for monitoring the impact of ocean
473 acidification and global warming on coral calcification rates. This cheap, inexpensive, quick
474 and straightforward method is appropriate for large scale studies. This method could also be
475 applied on paleo-environmental / climatic studies.

476

477 ***Acknowledgments***

478

479 The authors thank the radiology staff of Jean Verdier hospital (Bondy, Seine Saint Denis,
480 France) for their professional help and patience with computerized x-radiographs and CT
481 scans. We thank Claire E. Lazareth, Henning Kuhnert, Ruth Gingold, Marielle Dumestre,
482 Christine Omuombo, Mercedes Mendez-Millan and two anonymous reviewers for their
483 relevant corrections and comments.

484 Coral sample R_s was drilled with funds provided by the Vice-rectory of Investigation of the
485 University of Costa Rica (project 808-A8-602) during an internship (N.D.), facilitated by the
486 exchange program of the University of La Rochelle and the University of Costa Rica a

487 program supported by the “Bourse régionale de la découverte” (région Poitou-Charentes).
488 Coral sample R_p was collected during a field trip done in the framework of the HOLBECO
489 project, supported by the French INSU-EC2CO program (managed by the IFREMER
490 Institute).
