Preliminary results for the study of the Godunov Scheme Applied to the Linear Wave Equation with Porosity at Low Mach Number

Stéphane Dellacherie∗, Jonathan Jung† and Pascal Omnes‡

December 3, 2014

Abstract

We introduce continuous tools to study the low Mach number behaviour of the Godunov scheme applied to the linear wave equation with porosity on cartesian meshes. More precisely, we extend the Hodge decomposition to a weighted $L^2$ space in the continuous case and we study the properties of the modified equation associated to this Godunov scheme. This allows to partly explain the inaccuracy of the Godunov scheme at low Mach number on cartesian meshes and to propose two corrections: a first one named low Mach and a second one named all Mach. These results are preliminary since it remains to prove them in the discrete case.

1 Linear wave equation with porosity

The dimensionless barotropic Euler system with porosity may be written as

\[
\begin{align*}
\partial_t (\alpha \rho) + \nabla \cdot (\alpha \rho \mathbf{u}) &= 0, \\
\partial_t (\alpha \rho \mathbf{u}) + \nabla \cdot (\alpha \rho \mathbf{u} \otimes \mathbf{u}) + \frac{\alpha}{M^2} \nabla p &= 0.
\end{align*}
\]

In (1), $M$ is the Mach number that is supposed to be small and $\alpha(x)$ is the porosity, $t \geq 0$ and $x \in \Omega$ are respectively the time and space variables. The quantities $\rho$, $\mathbf{u}$ and $p(\rho)$ are respectively the density, the velocity field and the pressure law of the fluid. We assume that the pressure law satisfies $p'(\rho) > 0$ and that $\alpha(x)$ is a known function that takes its values in $[\alpha_{\text{min}}, 1]$, where $\alpha_{\text{min}} > 0$ is a constant which does not depend on $M$.

When the geometry is 2D or 3D and the cells of the mesh are not triangular (in 2D) nor tetrahedral (in 3D), finite volume Godunov type schemes applied to (1) with periodic boundary conditions are known to be inaccurate at low Mach number when $\nabla \alpha = 0$ [1, 5, 3], contrarily to staggered schemes on cartesian meshes [5, 6]. To better understand this behaviour when $\nabla \alpha \neq 0$ and to propose a low Mach correction (when it is necessary) and an all Mach correction (when we want to recover the Godunov scheme for Mach numbers of order one) in the spirit of what is done in [3], we introduce tools adapted to a linearization of (1) around $(\rho = \rho_*, \mathbf{u} = 0)$ when $\Omega$ is periodic and we extend to the 2D/3D case some 1D results proposed in [4]. For this purpose, we set the reference sound speed to $\frac{a_\star^2}{M}$ ($a_\star^2 = p'(\rho_*)$) and we define $r(t, \mathbf{x})$ such as

\[
\rho(t, \mathbf{x}) := \rho_* \left( 1 + \frac{M}{a_\star^2} r(t, \mathbf{x}) \right)
\]

where formally $\frac{M}{a^*} r \ll 1$. By injecting (2) in (1), we obtain the system

$$
\begin{align*}
\partial_t (\alpha r) + \nabla \cdot (\alpha r \mathbf{u}) + \frac{a^*_*}{M} \nabla \cdot (\alpha \mathbf{u}) &= 0, \\
\partial_t (\alpha \mathbf{u}) + (\alpha \mathbf{u} \cdot \nabla) \mathbf{u} + \frac{\alpha}{M} \rho' \left( 1 + \frac{M}{a^*} r \right) \nabla r &= 0.
\end{align*}
$$

By linearizing around $(r, \mathbf{u}) = (0, 0)$, we obtain the linear wave equation with porosity

$$
\partial_t (\alpha q) + \frac{L_\alpha}{M}(q) = 0 \quad \text{where} \quad q = \begin{pmatrix} r \\ \mathbf{u} \end{pmatrix} \quad \text{and} \quad L_\alpha(q) = a^* \left( \frac{\nabla \cdot (\alpha \mathbf{u})}{\alpha \nabla r} \right). \quad (3)
$$

## 2 Weighted spaces $\mathcal{E}_\alpha$ and $\mathcal{E}_\alpha^\perp$

We are interested in the properties of System (3) solved on a torus $\mathbb{T} \subset \mathbb{R}^d$ (that is to say with periodic boundary conditions). For this, we assume that $\alpha$ is a periodic function on $\mathbb{T}$ and we define the weighted Hilbert space

$$
L_\alpha^2(\mathbb{T})^{1+d} := \left\{ q := (r, \mathbf{u})^T \bigg| \int_\mathbb{T} r^2 dx + \int_\mathbb{T} |\mathbf{u}|^2 dx < +\infty \right\}
$$

endowed with the scalar product

$$
(q_1, q_2)_\alpha = \int_\mathbb{T} r_1 r_2 dx + \int_\mathbb{T} \mathbf{u}_1 \cdot \mathbf{u}_2 dx. \quad (4)
$$

Of course, the space $L_\alpha^2$ must not be confused with the acoustic operator $L_\alpha$. We use the same notation to define the spaces $H_\alpha^1(\mathbb{T})$ and $H_\alpha^2(\mathbb{T})$ that are generalizations of $H^1(\mathbb{T})$ and $H^2(\mathbb{T})$ to weighted spaces. We note that since $\alpha(x) \in [a_{\text{min}}, 1]$ with $a_{\text{min}} > 0$, the functions $\alpha$ and $\frac{1}{\alpha}$ are in $L^\infty(\mathbb{T})$, and we have $L_\alpha^2(\mathbb{T}) = L^2(\mathbb{T})$, $H_\alpha^1(\mathbb{T}) = H^1(\mathbb{T})$ and $H_\alpha^2(\mathbb{T}) = H^2(\mathbb{T})$. Nevertheless, we keep the index $\alpha$ to define these spaces to refer to the scalar product (4). At last, we define the space

$$
\mathcal{E}_\alpha := \left\{ q = (r, \mathbf{u})^T \in L_\alpha^2(\mathbb{T})^{1+d} \bigg| \nabla r = 0 \quad \text{and} \quad \nabla \cdot (\alpha \mathbf{u}) = 0 \right\} = \text{Ker } L_\alpha.
$$

When $\alpha = 1$, $\mathcal{E}_\alpha$ is named the incompressible space (see [1]). We have the following result:

**Lemma 2.1.** We have

$$
\mathcal{E}_\alpha^\perp = \left\{ q = (r, \mathbf{u})^T \in L_\alpha^2(\mathbb{T})^{1+d} \bigg| \int_\mathbb{T} r dx = 0 \quad \text{and} \exists \phi \in H_\alpha^1(\mathbb{T}), \quad \mathbf{u} = \nabla \phi \right\}, \quad (5)
$$

$$
\mathcal{E}_\alpha \oplus \mathcal{E}_\alpha^\perp = L_\alpha^2(\mathbb{T})^{1+d}. \quad (6)
$$

In other words, any $q = (r, \mathbf{u})^T \in L_\alpha^2(\mathbb{T})^{1+d}$ can be decomposed into

$$
q = \hat{q} + q^\perp \quad (7)
$$

where $\hat{q} = (\hat{r}, \hat{\mathbf{u}})^T \in \mathcal{E}_\alpha$ and $q^\perp = (r^\perp, u^\perp)^T \in \mathcal{E}_\alpha^\perp$, this decomposition is unique and orthogonal with respect to the scalar product defined by (4).

We call $\mathcal{E}_\alpha^\perp$ the acoustic space. This is a generalization of the Hodge decomposition to the weighted space $L_\alpha^2(\mathbb{T})^{1+d}$. The decomposition (7) defines the orthogonal projection

$$
P_\alpha : L_\alpha^2(\mathbb{T})^{1+d} \longrightarrow \mathcal{E}_\alpha \quad q \longmapsto P_\alpha q := \hat{q}. \quad (8)
$$

**Proof.** We firstly prove (5). We note $A$ the space

$$
A := \left\{ q = (r, \mathbf{u})^T \in L_\alpha^2(\mathbb{T})^{1+d} \bigg| \int_\mathbb{T} r dx = 0 \quad \text{and} \exists \phi \in H_\alpha^1(\mathbb{T}), \quad \mathbf{u} = \nabla \phi \right\}.
$$

 Firstly, we prove that $A \subset \mathcal{E}_\alpha^+$ and, secondly, we prove that $\mathcal{E}_\alpha^+ \subset A$. Let $q_1 = (r_1, u_1)^T \in A$. For all $q_2 = (r_2, u_2)^T \in \mathcal{E}_\alpha$, we have

$$\langle q_1, q_2 \rangle_{\mathcal{E}} = \int_T r_1 r_2 d\sigma + \int_T u_1 \cdot u_2 d\sigma = r_2 \int_T r_1 d\sigma + \int_T \nabla \phi_1 \cdot u_2 d\sigma$$

$$= 0 + \int_{\partial T} \phi_1 (\alpha u_2) \cdot n d\sigma - \int_{\partial T} \phi_1 \nabla \cdot (\alpha u_2) d\sigma = \int_{\partial T} \phi_1 (\alpha u_2) \cdot n d\sigma = 0$$

because $q_2 \in \mathcal{E}_\alpha$ and $\phi_1 (\alpha u_2)$ is periodic. This proves that $A \subset \mathcal{E}_\alpha^+$. Let $q_1 = (r_1, u_1)^T \in \mathcal{E}_\alpha^+$. For all $q_2 = (r_2, u_2)^T \in \mathcal{E}_\alpha$, we have

$$\langle q_1, q_2 \rangle_{\mathcal{E}} = 0 \implies \int_T r_1 r_2 d\sigma + \int_T u_1 \cdot u_2 d\sigma = 0 \implies r_2 \int_T r_1 d\sigma + \int_T u_1 \cdot (\alpha u_2) d\sigma = 0.$$

Then $\int_T r_1 d\sigma = 0$ and $\int_T u_1 \cdot (\alpha u_2) d\sigma = 0$ for all $u_2 \in L_\alpha^2 (\mathbb{T})^d$ such that $\nabla \cdot (\alpha u_2) = 0$. Moreover, since $\alpha$ and $\frac{1}{\alpha}$ are in $L^\infty (\mathbb{T})$, the last equality is equivalent to $\int_T u_1 \cdot \hat{u}_2 d\sigma = 0$ for all $\hat{u}_2 \in \mathcal{E} := \{u \in L^2 (\mathbb{T})^d : \nabla \cdot u = 0\}$. Therefore, $u_1 \in \mathcal{E}^\perp$ for the classical $L_\alpha^2 (\mathbb{T})^d$ scalar product. It is a classical result that

$$\mathcal{E}^\perp = \{u \in L^2 (\mathbb{T})^d : \exists \phi \in H^1 (\mathbb{T}), u = \nabla \phi\}.$$  

This implies that $\exists \phi_1 \in H^1_\alpha (\mathbb{T})$ such that $u_1 = \nabla \phi_1$, which allows to write that $\mathcal{E}_\alpha^+ \subset A$. To conclude, we have $\mathcal{E}_\alpha^+ = A$.

Now, we prove (6). Since the inclusion $\subset$ is trivial, we just have to prove that $\mathcal{E}_\alpha \oplus \mathcal{E}_\alpha^+ \supset L_\alpha^2 (\mathbb{T})^{1+d}$. Let $q = (r, u)^T \in L_\alpha^2 (\mathbb{T})^{1+d}$. We dissociate the construction of $(\hat{r}, \hat{r}^\perp)$ from that of $(\hat{u}, \hat{u}^\perp)$. For $r$, we can define $\hat{r} = \frac{1}{\int_T r d\sigma} \int_T r d\sigma$ since $\alpha \geq \alpha_{\text{min}} > 0$ implies that $\int_T r d\sigma > 0$. Moreover, $\alpha \in [0,1]$ implies that $\int_T \alpha d\sigma \leq \|\alpha\|_{\infty} |\mathbb{T}| \leq +\infty$ and with the Cauchy-Schwarz inequality, we obtain

$$\left| \int_T r d\sigma \right| \leq \left( \int_T r^2 d\sigma \right)^\frac{1}{2} \left( \int_T \alpha d\sigma \right)^\frac{1}{2} \leq \|r\|_{L_\alpha^2} \|\alpha\|^\frac{1}{2} |\mathbb{T}|^\frac{1}{2} < +\infty.$$ 

Then, since

$$\int_T (r - \hat{r}) d\sigma = \int_T r d\sigma - \hat{r} \int_T d\sigma = 0,$$

we can write $r = \hat{r} + (r - \hat{r})$ with $\nabla \hat{r} = 0$ and $\int_T (r - \hat{r}) d\sigma = 0$ which gives the decomposition for $r$. For $u$, the construction is slightly more difficult. We want to construct $\hat{u}$ and $\nabla \phi$ such that $u = \hat{u} + \nabla \phi$ with $\nabla \cdot (\alpha \hat{u}) = 0$. It is then sufficient to prove that there exists $\phi \in H^1_\alpha (\mathbb{T})$ such that

$$\begin{cases}
\nabla \cdot (\alpha \nabla \phi) = \nabla \cdot (\alpha u),

\int_T \phi d\sigma = 0
\end{cases}$$ (9)

and to set $\hat{u} = u - \nabla \phi$. We note $H^1_{\alpha,0} (\mathbb{T}) \subset H^1_\alpha (\mathbb{T})$ the subset of functions $\phi$ such that $\int_T \phi d\sigma = 0$. We write (9) under variational form:

Find $\phi \in H^1_{\alpha,0} (\mathbb{T})$ such that $\forall \psi \in H^1_{\alpha,0} (\mathbb{T}) : a(\phi, \psi) := \int_T (\alpha \nabla \phi) \cdot \nabla \psi d\sigma = \int_T (\alpha u) \cdot \nabla \psi d\sigma = : L(\psi)$.

Moreover, $L$ is a continuous linear functional on the Hilbert space $H^1_{\alpha,0} (\mathbb{T})$ because

$$|L(\psi)| \leq \int_T \sqrt{\alpha} u \cdot \sqrt{\alpha} \nabla \psi d\sigma \leq \|u\|_{L_2} \|\nabla \psi\|_{L_2} \leq \|u\|_{L_2} \|\psi\|_{H^1}.$$  

By using a similar argument, we also prove that $a(\cdot, \cdot)$ is a symmetric bilinear form that is continuous on $H^1_{\alpha,0} (\mathbb{T})$. To prove the coercivity of $a$, we use a generalization of the Poincaré-Wirtinger inequality to the
probabilistic measure $\mu := \frac{\alpha^1}{\int_{x \in \mathbb{X}} f \, dx}$ on the convex space $T$ (see Appendix). As $\mu$ and $\frac{1}{\mu}$ are in $L^\infty(T)$, for $\phi \in H^1_\alpha(T)$ and $\tilde{\phi} := \frac{1}{\mu} \int_T \phi \, dx$, we have

$$\int_T |\phi - \tilde{\phi}|^2 \mu \, dx \leq 2 \text{diam}(T)^2 \|\mu\|_\infty \left\| \frac{1}{\mu} \right\|_\infty \int_T |\nabla \phi|^2 \mu \, dx$$

(10)

where $\text{diam}(T) := \sup_{(x,y) \in T^2} |x - y|$, which is equivalent to $\int_T |\phi - \tilde{\phi}|^2 \, dx \leq 2 \text{diam}(T)^2 \|\alpha\|_\infty \left\| \frac{1}{\alpha} \right\|_\infty \int_T |\nabla \phi|^2 \, dx$.

Thus, we can write that

$$C_\alpha(T) \int_T |\phi - \tilde{\phi}|^2 \, dx \leq \int_T |\nabla \phi|^2 \, dx$$

(11)

with $C_\alpha(T) := \frac{1}{2 \text{diam}(T)^2 \|\alpha\|_\infty \left\| \frac{1}{\alpha} \right\|_\infty} > 0$. For $\phi \in H^1_{\alpha,0}(T)$, we have $\tilde{\phi} = 0$ and we can write

$$a(\phi, \phi) = \int_T |\nabla \phi|^2 \, dx = \frac{1}{2} \int_T |\nabla \phi|^2 \, dx + \frac{1}{2} \int_T |\nabla \phi|^2 \, dx$$

$$\geq \frac{1}{2} \int_T |\nabla \phi|^2 \, dx + \frac{C_\alpha(T)}{2} \int_T |\phi|^2 \, dx \geq \frac{1}{2} \min (1, C_\alpha(T)) \|\phi\|_{H^2_\alpha}^2$$

which means that $a(\cdot, \cdot)$ is coercive. Then, by applying the Lax-Milgram theorem, we obtain the existence of a unique function $\phi$ in $H^1_{\alpha,0}(T)$ such that $\forall \psi \in H^1_{\alpha,0}(T)$, $a(\phi, \psi) = L(\psi)$ that is to say

$$\forall \psi \in H^1_{\alpha,0}(T) : \int_T (\alpha \nabla \phi) \cdot \nabla \psi \, dx = \int_T (\alpha u) \cdot \nabla \psi \, dx.$$  

(12)

We note $D(T)$ the set of functions $C^\infty(T)$ with a compact support. For all $\psi$ in $D(T)$, the function

$$\tilde{\psi} := \psi - \bar{\psi} := \psi - \frac{\int_T \psi \, dx}{\int_T \alpha \, dx}$$

is in $H^1_{\alpha,0}(T)$. Then, $\tilde{\psi}$ satisfies (12). And since $\nabla \tilde{\psi} = \nabla \psi$, we have

$$\forall \psi \in D(T) : \int_T (\alpha \nabla \phi) \cdot \nabla \psi \, dx = \int_T (\alpha u) \cdot \nabla \psi \, dx$$

that is to say

$$\forall \psi \in D(T) : \langle - \nabla \cdot (\alpha \nabla \phi), \psi \rangle_{D,D'} = \langle - \nabla \cdot (\alpha u), \psi \rangle_{D,D'}.$$  

In other words, $\nabla \cdot (\alpha \nabla \phi) = \nabla \cdot (\alpha u)$ in the sense of distribution. By setting $u = u - \nabla \phi$, we obtain $u = \bar{u} + \nabla \phi$ with $\nabla \cdot (\alpha \bar{u}) = 0$. Thus $L^2_{\alpha}(T)^{1+d} \subset E_\alpha \oplus E_\alpha^\perp$. □

3 Properties of the linear wave equation with porosity

We now detail some properties of the linear wave equation with porosity. These properties will not be always satisfied in the discrete case.

**Lemma 3.1.** Let $q(t, x)$ be the solution of (3) on $T \subset \mathbb{R}^{d \times (1,2,3)}$ with initial condition $q^0$. Then:

1) $\forall q^0 \in \mathcal{E}_\alpha : q(t \geq 0) \in \mathcal{E}_\alpha$.

2) $\forall q^0 \in \mathcal{E}_\alpha^\perp : q(t \geq 0) \in \mathcal{E}_\alpha^\perp$.
Proof. The first point is a direct consequence of the expression of System (3) because \( E_\alpha = \text{Ker} L_\alpha \) and then for all \( t \geq 0 \), \( q(t) = q^0 \). Let \( q^0 = (r^0, u^0)^T \in E_\alpha^0 \). We have \( \alpha q(t) = \alpha q^0 - \frac{1}{M} \int_0^t L_\alpha(q) dt \). Then, for all \( \tilde{q} = (\tilde{r}, \tilde{u})^T \in E_\alpha \), we have

\[
\langle q, \tilde{q} \rangle_\alpha = \langle q^0, \tilde{q} \rangle_\alpha - \frac{1}{M} \int_0^t \int_\Gamma L_\alpha(q) \cdot \tilde{q} \, dx \, ds
\]

with

\[
\int_\Gamma L_\alpha(q) \cdot \tilde{q} \, dx = a_* \int_\Gamma (\nabla \cdot (\alpha u) \tilde{r} + \alpha \nabla \tilde{r} \cdot \tilde{u}) \, dx = -a_* \int_\Gamma ((\alpha u) \cdot \nabla \tilde{r} + r \nabla \cdot (\alpha \tilde{u})) \, dx = 0
\]

because \( \tilde{q} \in E_\alpha = \text{Ker} L_\alpha \). Then, for all \( \tilde{q} = (\tilde{r}, \tilde{u})^T \in E_\alpha \), \( \langle q, \tilde{q} \rangle_\alpha = \langle q^0, \tilde{q} \rangle_\alpha = 0 \) which means that \( q \in E_\alpha^\perp \). \( \square \)

For all \( q \in L_\alpha^0 (\mathbb{T})^{1+d} \), we now define the energy \( E_\alpha := \langle q, q \rangle_\alpha \). The following lemma is an extension of the energy conservation property of the classical linear wave equation:

Lemma 3.2. Let \( q(t, x) \) be the solution of (3) on \( \mathbb{T} \subset \mathbb{R}^{d\varepsilon(1,2,3)} \). Then:

\[ \forall t \geq 0 : \quad E_\alpha (t \geq 0) = E_\alpha (t = 0). \]

Proof. For a solution \( q = (r, u)^T \) of System (3), we have

\[ \partial_t (\alpha q) + \frac{L_\alpha}{M} (q) = 0 \Rightarrow \frac{d}{dt} \langle q, q \rangle_\alpha + \langle q \cdot \frac{L_\alpha}{M} (q) \rangle_\alpha = 0 = \frac{d}{dt} E_\alpha (t) = 0 \]

because

\[
\langle q \cdot \frac{L_\alpha}{M} (q) \rangle_\alpha = \frac{a_*}{M} \int_\Gamma \left( \frac{r}{\alpha} \nabla \cdot (\alpha u) + \frac{u}{\alpha} \cdot (\alpha \nabla r) \right) \alpha \, dx = \frac{a_*}{M} \int_{\partial \mathbb{T}} u (\alpha u) \cdot n \, ds = 0 \quad (13)
\]

by using the periodicity of \( \mathbb{T} \). \( \square \)

4 Godunov scheme with porosity

We construct the Godunov scheme with porosity.

4.1 Finite volume scheme and Riemann problem

Let us suppose that the domain \( \mathbb{T} \subset \mathbb{R}^{d\varepsilon(1,2,3)} \) is discretized by \( N \) cells \( \Omega_i \). Let \( \Gamma_{ij} \) be the common edge (in 2D and common face in 3D) of the two neighboring cells \( \Omega_i \) and \( \Omega_j \) and \( \mathbf{n}_{ij} \) the unit vector normal to \( \Gamma_{ij} \) pointing from \( \Omega_i \) to \( \Omega_j \). We assume that the quantities \( \alpha, \mathbf{r}, \alpha \mathbf{u} \) are defined on the cells \( \Omega_i \) by

\[
\alpha_i = \frac{1}{|\Omega_i|} \int_{\Omega_i} \alpha \, dx, \quad (\alpha \mathbf{r})_i = \frac{1}{|\Omega_i|} \int_{\Omega_i} \mathbf{r} \, dx, \quad (\alpha \mathbf{u})_i = \frac{1}{|\Omega_i|} \int_{\Omega_i} \alpha \mathbf{u} \, dx.
\]

The semi-discrete finite volume scheme applied to the resolution of the linear wave equation with porosity (3) is given by

\[
\begin{aligned}
\frac{d}{dt} (\alpha \mathbf{r})_i + \frac{a_*}{M |\Omega_i|} \sum_{\Gamma_{ij} \subset \partial \Omega_i} |\Gamma_{ij}| (\alpha \mathbf{u} \cdot \mathbf{n}_{ij}) = 0, \\
\frac{d}{dt} (\alpha \mathbf{u})_i + \frac{a_*}{M |\Omega_i|} \sum_{\Gamma_{ij} \subset \partial \Omega_i} |\Gamma_{ij}| \mathbf{r}_{ij} \mathbf{n}_{ij} = 0.
\end{aligned}
\]

(14)
The Godunov approach consists in defining \( (r_{ij}, (\alpha u \cdot n)_{ij}) \) as the solution of the 1D Riemann problem in the \( n_{ij} \) direction on \( \xi/t = 0 \)

\[
\begin{cases}
\alpha_{ij} \partial_t r_{ij} + \frac{a_s}{M} \partial_t ((\alpha u)_{ij}) = 0, \\
\partial_t ((\alpha u)_{ij}) + \frac{a_s}{M} \alpha_{ij} \partial_t r_{ij} = 0, \\
(r_{ij}, (\alpha u)_{ij}) (t = 0, \xi) = \begin{cases} (r_i, (\alpha u)_i \cdot n_{ij}) & \text{if } \xi < 0, \\
(r_j, (\alpha u)_j \cdot n_{ij}) & \text{otherwise}
\end{cases}
\end{cases}
\]

(15)

where \( \xi \) is the coordinate in the \( n_{ij} \) direction and \( \alpha_{ij} \) is a mean value of \( \alpha \) on \( \Gamma_{ij} \) which depends on \( (\alpha_i, \alpha_j) \) (e.g. \( \alpha_{ij} = \frac{\alpha_i + \alpha_j}{2} \)).

### 4.2 Solution of the Riemann problem

We explicit the solution of the Riemann problem (15). By a simple scaling argument, the solution of (15) is a function only of \( \xi/t \). We set \( U = (r, J)^T \) where \( J = \alpha u \) and we write (15) under the form

\[
\partial_t U + A \partial_x U = 0, \quad \text{where } A = \begin{bmatrix} 0 & \frac{a_s}{M \alpha_{ij}} \\ \frac{a_s \alpha_{ij}}{M} & 0 \end{bmatrix}.
\]

System (15) is hyperbolic and the matrix \( A \) admits the two distinct eigenvalues \( \lambda_1 = -\frac{a_s}{M} < \lambda_2 = \frac{a_s}{M} \). The solution \( R(U_i, U_j, \xi/t) \) of (15) is under the form

\[
R(U_i, U_j, \xi/t) = \begin{cases} U_i, & \text{if } \xi/t < \lambda_1, \\
U^*, & \text{if } \lambda_1 < \xi/t < \lambda_2, \\
U_j, & \text{if } \xi/t > \lambda_2,
\end{cases}
\]

with

\[
U_i := (r_i, (\alpha u)_i \cdot n_{ij}) \quad \text{and} \quad U_j := (r_j, (\alpha u)_j \cdot n_{ij})
\]

and where we have to find \( U^* \). We use the Riemann invariants to explicit \( U^* = (r^*, J^*)^T \). We can prove that 

\[
\nu_1 = (1, -\alpha_{ij})^T \quad \text{(resp. } \nu_2 = (1, \alpha_{ij})^T) \quad \text{is an eigenvector of} \quad A \quad \text{associated to} \quad \lambda_1 \quad \text{(resp. } \lambda_2 \text{)}
\]

and that \( R_1 = J + \alpha_{ij} r \) is a 1-Riemann invariant and \( R_2 = J - \alpha_{ij} r \) is a 2-Riemann invariant. As a Riemann invariant is constant through a linearly degenerate wave, we obtain

\[
\begin{cases}
J^* + \alpha_{ij} r^* = J_i + \alpha_{ij} r_i, \\
J^* - \alpha_{ij} r^* = J_j - \alpha_{ij} r_j
\end{cases} \quad \implies \quad \begin{cases}
r^* = \frac{r_i + r_j}{2} + \frac{1}{2 \alpha_{ij}} (J_i - J_j), \\
J^* = \frac{J_i + J_j}{2} + \frac{\alpha_{ij}}{2} (r_i - r_j).
\end{cases}
\]

(16)

### 4.3 The Godunov scheme

Finally, setting in (14) \( r_{ij} = r^* \) and \( (\alpha u \cdot n)_{ij} = J^* \) given by (16), the Godunov scheme is given by

\[
\begin{align*}
\frac{d}{dt} (\alpha r)_i + \frac{a_s}{2M} \sum_{\Gamma_{ij} \in \partial Q_i} |\Gamma_{ij}| \left[ ((\alpha u)_i + (\alpha u)_j) \cdot n_{ij} + \alpha_{ij} (r_i - r_j) \right] &= 0, \\
\frac{d}{dt} (\alpha u)_i + \frac{a_s}{2M} \sum_{\Gamma_{ij} \in \partial Q_i} |\Gamma_{ij}| \left[ r_i + r_j + \frac{\kappa}{\alpha_{ij}} ((\alpha u)_i - (\alpha u)_j) \cdot n_{ij} \right] n_{ij} &= 0
\end{align*}
\]

(17)

where \( \kappa = 1 \). We introduce the parameter \( \kappa \) because this parameter will be important in the sequel.
Kernel of the first order modified equation on a cartesian mesh

To understand the behaviour of the Godunov scheme at low Mach number, a first step is to study the kernel of the spatial operator associated to the modified equation related to the Godunov scheme. Indeed, we will see that this kernel is strictly included in the kernel of the acoustic operator in (3) which is exactly equal to \( \mathcal{E}_\alpha \). As a consequence, the Godunov scheme does not preserve some states in \( \mathcal{E}_\alpha \).

5.1 First order modified equation on a cartesian mesh

We suppose for the sake of simplicity that the space dimension is 2. Assume that the mesh is cartesian with the space step \( \Delta x \) (resp. \( \Delta y \)) in the \( x \) (resp. \( y \)) direction. The subscript \((i, j)\) defines the center of each cell of the cartesian mesh, \((i \pm \frac{1}{2}, j)\) and \((i, j \pm \frac{1}{2})\) defining the interfaces of the cell \((i, j)\). The Godunov scheme (17) can be written with

\[
\frac{d}{dt} (\alpha u)_i,j + \frac{a_*}{M} \alpha_1,j \frac{r_{i+1,j} - r_{i-1,j}}{2\Delta x} = \kappa a_* \frac{\alpha_1,j}{2M} \left( \begin{array}{c} 1 \alpha_{i+\frac{1}{2},j} \left( (\alpha u)_i,j+1 - (\alpha u)_i,j \right) \\ - \frac{1}{\alpha_{i-\frac{1}{2},j}} \left( (\alpha u)_i,j - (\alpha u)_i,j-1 \right) \end{array} \right),
\]

and

\[
\frac{d}{dt} (\alpha u)_i,j + \frac{a_*}{M} \alpha_1,j \frac{r_{i,j+1} - r_{i,j-1}}{2\Delta y} = \kappa a_* \frac{\alpha_1,j}{2M} \left( \begin{array}{c} 1 \alpha_{i,j+\frac{1}{2}} \left( (\alpha u)_i,j+1 - (\alpha u)_i,j \right) \\ - \frac{1}{\alpha_{i,j-\frac{1}{2}}} \left( (\alpha u)_i,j - (\alpha u)_i,j-1 \right) \end{array} \right),
\]

with \( \kappa = 1 \). The first order modified equation associated to this scheme is given by

\[
\partial_t (\alpha q) + \frac{\mathcal{L}_{\kappa,\alpha}}{M}(q) = 0
\]

(18)

where \( \mathcal{L}_{\kappa,\alpha} = L_\alpha - MB_{\kappa,\alpha} \) with

\[
L_\alpha(q) = a_* \left( \nabla \cdot \frac{(\alpha u)}{\alpha \nabla \rho} \right) \quad \text{and} \quad B_{\kappa,\alpha}(q) = \begin{bmatrix} \frac{a_* \Delta x}{2M} \partial_x (\alpha \partial_x \rho) + \frac{a_* \Delta y}{2M} \partial_y (\alpha \partial_y \rho) \\ \kappa a_* \frac{\Delta x}{2M} \partial_x \left( \frac{1}{\alpha} \partial_x (\alpha u_x) \right) \\ \kappa a_* \frac{\Delta y}{2M} \partial_y \left( \frac{1}{\alpha} \partial_y (\alpha u_y) \right) \end{bmatrix}.
\]

5.2 Kernel of the modified equation and energy relation

We study the kernel of the spatial operator associated to the modified equation (18). The structure of the kernel depends on the value of \( \kappa \). The kernel for the Godunov scheme \((\kappa = 1)\) is different from the incompressible space \( \mathcal{E}_\alpha \). Indeed:

Lemma 5.1. 1. If \( \kappa > 0 \), we have

\[
\text{Ker} \mathcal{L}_{\kappa > 0,\alpha} = \{ q := (r, u)^T | \nabla r = 0 \text{ and } \partial_x (\alpha u_x) = \partial_y (\alpha u_y) = 0 \} \subseteq \mathcal{E}_\alpha.
\]

2. If \( \kappa = 0 \), we have

\[
\text{Ker} \mathcal{L}_{\kappa = 0,\alpha} = \mathcal{E}_\alpha.
\]
Proof. If $\kappa = 0$, we easily obtain that $\text{Ker} \mathcal{L}_{\kappa=0,\alpha} = \mathcal{E}_\alpha$. Let us now suppose that $\kappa > 0$. By using (13), we can write that

$$\left\langle \frac{q}{\alpha}, \mathcal{L}_{\kappa,\alpha}(q) \right\rangle_\alpha = \left\langle \frac{q}{\alpha}, B_{\kappa,\alpha}(q) \right\rangle_\alpha.$$ 

Let us choose $q := (r, u)^T \in \text{Ker} \mathcal{L}_{\kappa,\alpha}$. In that case, we deduce from the previous equality that

$$\left\langle \frac{q}{\alpha}, B_{\kappa,\alpha}(q) \right\rangle_\alpha = 0.$$ 

On the other hand, we have

$$- \left\langle \frac{q}{\alpha}, B_{\kappa,\alpha}(q) \right\rangle_\alpha = \frac{a_s \Delta x}{2M} \|\partial_x r\|_{L^2_{\alpha}}^2 + a_s \Delta y \|\partial_y r\|_{L^2_{\alpha}}^2 + \frac{\kappa a_s \Delta x}{2M} \left\| \frac{\partial_x (\alpha u_x)}{\alpha} \right\|_{L^2_{\alpha}}^2 + \frac{\kappa a_s \Delta y}{2M} \left\| \frac{\partial_y (\alpha u_y)}{\alpha} \right\|_{L^2_{\alpha}}^2. \quad (20)$$

This allows to write that

$$\|\partial_x r\|_{L^2_{\alpha}}^2 = \|\partial_y r\|_{L^2_{\alpha}}^2 = \left\| \frac{\partial_x (\alpha u_x)}{\alpha} \right\|_{L^2_{\alpha}}^2 = \left\| \frac{\partial_y (\alpha u_y)}{\alpha} \right\|_{L^2_{\alpha}}^2 = 0$$

that is to say $\nabla r = 0$ and $\partial_x (\alpha u_x) = \partial_y (\alpha u_y) = 0$. This proves that $\text{Ker} \mathcal{L}_{\kappa,\alpha} \subset \mathcal{A}$ with

$$\mathcal{A} := \{ q := (r, u)^T | \nabla r = 0 \text{ and } \partial_x (\alpha u_x) = \partial_y (\alpha u_y) = 0 \}.$$ 

Let us now suppose that $q \in \mathcal{A}$. In that case, we have $q \in \mathcal{E}_\alpha = \text{Ker} L_\alpha$ and $q \in \text{Ker} B_{\kappa,\alpha}$ that is to say $q \in \text{Ker} (L_\alpha - MB_{\kappa,\alpha}) = \text{Ker} \mathcal{L}_{\kappa,\alpha}$. Thus, we have also $\mathcal{A} \subset \text{Ker} \mathcal{L}_{\kappa,\alpha}$. \qed

If the kernel depends on the value of $\kappa$, System (18) is dissipative for all $\kappa \geq 0$. Indeed:

**Lemma 5.2.** Let $q(t, x)$ be the solution of (18) on $\mathbb{T} \subset \mathbb{R}^2$. If $\kappa \geq 0$, System (18) is dissipative. That is to say:

$$\forall t \geq 0 : \frac{d}{dt} E_\alpha(t) \leq 0 \quad \text{where} \quad E_\alpha(t) := \|q\|_{L^2_{\alpha}}^2.$$ 

Proof. We have

$$\frac{1}{2} \frac{d}{dt} E_\alpha(t) = - \left\langle \frac{q}{\alpha}, \mathcal{L}_{\kappa,\alpha}(q) \right\rangle_\alpha. \quad \text{And since} \quad \left\langle \frac{q}{\alpha}, \mathcal{L}_{\kappa,\alpha}(q) \right\rangle_\alpha = - \left\langle \frac{q}{\alpha}, B_{\kappa,\alpha}(q) \right\rangle_\alpha,$$

we obtain by using (20)

$$\frac{1}{2} \frac{d}{dt} E_\alpha(t) = - \frac{a_s}{2M} \left( \Delta x \|\partial_x r\|_{L^2_{\alpha}}^2 + \Delta y \|\partial_y r\|_{L^2_{\alpha}}^2 + \kappa \Delta x \left\| \frac{\partial_x (\alpha u_x)}{\alpha} \right\|_{L^2_{\alpha}}^2 + \kappa \Delta y \left\| \frac{\partial_y (\alpha u_y)}{\alpha} \right\|_{L^2_{\alpha}}^2 \right). \quad (21)$$

This equality allows to write that $\frac{d}{dt} E_\alpha(t) \leq 0$ for any $\kappa \geq 0$. \qed

## 6 Explanation of the inaccuracy of the Godunov scheme on a cartesian mesh at low Mach number by using the modified equation

We studied the kernel $\text{Ker} \mathcal{L}_{\kappa,\alpha}$ of the spatial operator associated to the Godunov scheme ($\kappa = 1$). This kernel is a subset of the incompressible space $\mathcal{E}_\alpha$. As a consequence, the Godunov scheme does not preserve any incompressible state $q \in \mathcal{E}_\alpha$. However, if we delete the numerical diffusion of the Godunov scheme on the velocity field by setting $\kappa = 0$, the kernel of the modified equation is exactly the incompressible space $\mathcal{E}_\alpha$. Thus, all the incompressible states $q \in \mathcal{E}_\alpha$ will be preserved over time. Nevertheless, the knowledge of $\text{Ker} \mathcal{L}_{\kappa,\alpha}$ gives only partial informations on the time behaviour of the solution of (18). In the sequel, we give the definition of an accurate scheme at low Mach number when its first order modified equation is (18) and we prove that the Godunov scheme is not accurate at low Mach number when $M \ll \min(\Delta x, \Delta y)$. 

6.1 Definition of an accurate scheme at low Mach number

We propose the following definition in order to clearly define an accurate scheme at low Mach number:

**Definition 6.1.** Scheme (17) is accurate at low Mach number if the solution \( q(t, x) \) of the modified equation (18) related to this scheme satisfies

\[
\forall (C_1, C_2) \in (\mathbb{R}_+^2)^2, \exists C_3 > 0 \text{ such that } ||q^0 - \mathbb{P}_\alpha q^0||_{L^2_2} = C_1 M \\
\implies \forall t \in [0, C_2 M], ||q - \mathbb{P}_\alpha q^0||_{L^2_2}(t) \leq C_3 M. \tag{22}
\]

We underline that \( C_3 \) does not depend on \( M \) and we recall that \( \mathbb{P}_\alpha \) is the orthogonal projection on \( \mathcal{E}_\alpha \) defined by (8).

This definition is justified by the fact that the solution of the linear wave equation (3) satisfies (22) (see [3] for an accurate justification of this definition).

6.2 Inaccuracy of the Godunov scheme at low Mach number

The following theorem – written in 2D for the sake of simplicity, the 3D case being similar – explains why the Godunov scheme applied to the linear wave equation with porosity on a cartesian mesh is not accurate at low Mach number:

**Theorem 6.2.** When

\[
\min(\Delta x, \Delta y) \leq \sqrt{2} \text{diam}(\mathcal{T}) \sqrt{||\alpha||_\infty \cdot \frac{1}{\alpha} ||y||_\infty}, \tag{23}
\]

for almost all initial conditions \( q^0 \in L^2_2(\mathcal{T})^3 \), the solution \( q(t, x) \) of (18) with \( \kappa = 1 \) verifies:

\[
\exists (C_2, C_3) \in (\mathbb{R}_+^2)^2 \text{ such that } \forall C_1 > 0, ||q^0 - \mathbb{P}_\alpha q^0||_{L^2_2} = C_1 M \\
\implies \forall t \geq C_2 M, ||q - \mathbb{P}_\alpha q^0||_{L^2_2}(t) \geq C_3 \min(\Delta x, \Delta y). \tag{24}
\]

for any \( M \leq \frac{C_3}{C_1} \min(\Delta x, \Delta y) \), \( C_2 \) and \( C_3 \) being positive parameters that do not depend on \( M, \Delta x \) and \( \Delta y \).

This result – which is a generalization of Theorem 3.1 in [3] obtained with a constant porosity – shows that the Godunov scheme is not accurate at low Mach number when \( M \ll \min(\Delta x, \Delta y) \) (for almost all initial condition \( q^0 \)) since it does not verify (22). Let us note that (23) is verified when \( \min(\Delta x, \Delta y) \leq \sqrt{2} \text{diam}(\mathcal{T}) \) because

\[
0 < \alpha_{\text{min}} \leq \alpha_{\text{max}} \leq 1 \implies 0 < \alpha_{\text{min}} \leq \sqrt{\alpha_{\text{max}}} \implies \sqrt{\alpha_{\text{min}}} \leq \frac{\alpha_{\text{max}}}{\alpha_{\text{min}}} = \sqrt{||\alpha||_\infty \cdot \frac{1}{\alpha} ||y||_\infty}
\]

and that \( \min(\Delta x, \Delta y) \leq \sqrt{2} \text{diam}(\mathcal{T}) \) is easily satisfied (we underline that \( \alpha_{\text{min}} \) is of order one in the sense that \( M \ll \alpha_{\text{min}} \)).

6.3 Proof of Theorem 6.2

By linearity, the solution \( q(t, x) \) of (18) with the initial condition \( q^0 \) can be written as \( q(t, x) = q_1(t, x) + q_2(t, x), \) where \( q_1 \) is solution of

\[
\begin{aligned}
\partial_t (\alpha q_1) + \frac{\mathcal{L}_{\kappa, \alpha}}{M} (q_1) &= 0, \\
q_1(t = 0, x) &= (q^0 - \mathbb{P}_\alpha q^0)(x)
\end{aligned} \tag{25}
\]

and \( q_2 \) is the solution of

\[
\begin{aligned}
\partial_t (\alpha q_2) + \frac{\mathcal{L}_{\kappa, \alpha}}{M} (q_2) &= 0, \\
q_2(t = 0, x) &= \mathbb{P}_\alpha q^0(x).
\end{aligned} \tag{26}
\]
We have
\[ \forall t \geq 0, \quad \| q - P_\alpha q^0 \|_{L^2_t} = \| q_1 + q_2 - P_\alpha q^0 \|_{L^2_t} \geq \| q_2 - P_\alpha q^0 \|_{L^2_t} - \| q_1 \|_{L^2_t} \]
\[ \geq \| q_2 - P_\alpha q^0 \|_{L^2_t} - \| q_1 \|_{L^2_t} = \| q_2 - P_\alpha q^0 \|_{L^2_t} - \| q^0 - P_\alpha q^0 \|_{L^2_t} \]

because Equation (18) is dissipative when \( \kappa \geq 0 \) (see Lemma 5.2). Then, if \( \| q^0 - P_\alpha q^0 \|_{L^2_t} = C_1 M \), we only have to study the function \( t \mapsto \| q_2 - P_\alpha q^0 \|_{L^2_t} \), where \( q_2 \) is the solution of (26). The idea is to find a lower bound for the function \( t \mapsto \| q_2 - P_\alpha q^0 \|_{L^2_t} \). To do this, we need some tools:

- a projection \( P_{\kappa=1,\alpha} \) on \( \text{Ker} \ L_{\kappa=1,\alpha} \) where \( \text{Ker} \ P_{\kappa=1,\alpha} \) is invariant for Equation (18) (in the sense of (28)),
- we write \( q_2 - P_\alpha q^0 = q_2 - P_{\kappa=1,\alpha} P_\alpha q^0 + P_{\kappa=1,\alpha} P_\alpha q^0 - P_\alpha q^0 \),
- we verify that \( P_{\kappa=1,\alpha} (q_2 - P_{\kappa=1,\alpha} P_\alpha q^0) = 0 \),
- we use a Poincaré-Wirtinger inequality valid on \( \text{Ker} \ P_{\kappa=1,\alpha} \) for \( q_2 - P_{\kappa=1,\alpha} P_\alpha q^0 \),
- we verify that \( q_2 - P_{\kappa=1,\alpha} P_\alpha q^0 \) is solution of (18),
- we obtain the rate of dissipation of \( \| q_2 - P_{\kappa=1,\alpha} P_\alpha q^0 \| \) to zero by applying the Grönwall’s lemma.

**Lemma 6.3.** The function \( L^2_t(\mathbb{T})^d \to \text{Ker} \ L_{\kappa=1,\alpha} \)
\[ q = (r, u) \mapsto \begin{pmatrix} r \\ u \\ \int r \, dx \end{pmatrix} \]
\[ \Rightarrow \begin{pmatrix} \frac{1}{\alpha} \int_a^b r \, dx \\ \frac{1}{\alpha} \int_a^b \frac{u}{y(x,y)} \, dx \\ \frac{1}{\alpha} \int_a^b \frac{u}{y(x,y)} \, dy \end{pmatrix} \]
defines a projection \( P_{\kappa=1,\alpha} \). Moreover, if \( q(t, x) \) is the solution of (18) on \( \mathbb{T} \) with initial condition \( q^0 \):
\[ \forall q^0 \in \text{Ker} \ P_{\kappa=1,\alpha}, \quad q(t \geq 0) \in \text{Ker} P_{\kappa=1,\alpha}. \]  

**Proof.** Recall that \( \mathbb{T} = [a_1, b_1] \times [a_2, b_2] \). It is easy to prove that \( P_{\kappa=1,\alpha} \circ P_{\kappa=1,\alpha} = P_{\kappa=1,\alpha} \). This proves that \( P_{\kappa=1,\alpha} \) is a projector. Moreover, we have \( \text{Im} \ P_{\kappa=1,\alpha} \subset \text{Ker} \ L_{\kappa=1,\alpha} \) because for all \( q = (r, u) \in L^2_t(\mathbb{T})^{1+d} \),
\[ \nabla \left( \frac{1}{\alpha} \int_a^b r \, dx \right) = 0, \]
\[ \partial_x \left( \frac{1}{\alpha} \int_a^b u \, dx \right) = \partial_x \left( \frac{1}{\alpha} \int_a^b u \, dx \right) = 0, \]
\[ \partial_y \left( \frac{1}{\alpha} \int_a^b u \, dy \right) = \partial_y \left( \frac{1}{\alpha} \int_a^b u \, dy \right) = 0. \]

Let \( q(t, x) \) be a solution of (18) on \( \mathbb{T} \) with initial condition \( q^0 \in \text{Ker} P_{\kappa=1,\alpha} \). By integrating the first equation of system (18) on \( \mathbb{T} \), we obtain
\[ \frac{d}{dt} \int_{\mathbb{T}} r \, dx \, dy + \frac{a_x}{M} \int_{\mathbb{T}} \nabla \cdot (\alpha u) \, dx \, dy = \int_{\mathbb{T}} \left( \frac{a_x \Delta x}{2M} \partial_x (\alpha \partial_x r) + \frac{a_y \Delta y}{2M} \partial_y (\alpha \partial_y r) \right) \, dx \, dy \Rightarrow \frac{d}{dt} \int_{\mathbb{T}} \alpha r \, dx \, dy = 0 \]
by periodicity. Then, if \( \int_{\mathbb{T}} \alpha r \, dx \, dy = 0 \), it is the case at any time. Moreover, since \( \alpha \) does not depend on time, we can write the second equation of (18) under the form
\[ \partial_t u_x + \frac{a_x}{M} \partial_x r = \kappa \frac{a_x \Delta x}{2M} \partial_x \left( \frac{1}{\alpha} \partial_x (\alpha u_x) \right). \]
Lemma 6.4. For any $\mu \in \mathbb{R}$, we obtain (29) with (30), (31) and (32).

Proof. Let us define $\mu = 1/\alpha$. We now write a Poincaré-Wirtinger inequality for a function $q \in \text{Ker} \mathbb{P}_{\alpha=1,\alpha}$:

**Lemma 6.4.** For any $q := (r, u_x, u_y)^T \in \text{Ker} \mathbb{P}_{\alpha=1,\alpha}$ such that $(r, \alpha u_x, \alpha u_y)^T \in H_1(\mathbb{T})^3$, we have

$$
\|q\|_{L_2}^2 \leq K_\alpha(T)^2 \left( \|\nabla r\|_{L_2}^2 + \left\| \frac{\partial_x (\alpha u_x)}{\alpha} \right\|_{L_2}^2 + \left\| \frac{\partial_y (\alpha u_y)}{\alpha} \right\|_{L_2}^2 \right) \tag{29}
$$

with $K_\alpha(T) = \sqrt{\text{diam}(T)} |\alpha|_{\infty} \cdot |\frac{1}{\alpha}|_{\infty}$.

Proof. Let $q = (r, u_x, u_y)^T \in \text{Ker} \mathbb{P}_{\alpha=1,\alpha}$. Since $\int_{\mathbb{T}} r \, dx \, dy = 0$, by using the weighted Poincaré-Wirtinger inequality (11) on $r$, we obtain

$$
\|r\|_{L_2} \leq \frac{1}{\sqrt{C_\alpha(T)}} \|\nabla r\|_{L_2}, \tag{30}
$$

where $\sqrt{C_\alpha(T)} = 1/K_\alpha(T)$. Moreover, since for all $y \in [a_2, b_2]$, we have $0 = \int_{a_1}^{b_1} u_x(x, y) \, dx = \int_{a_1}^{b_1} (\alpha u_x)(x, y) \frac{1}{\alpha} \, dx$, by applying the weighted Poincaré-Wirtinger inequality (10) to the function $x \mapsto (\alpha u_x)(x, y)$ with the weight $\mu = 1/\alpha$, we obtain

$$
\int_{a_1}^{b_1} |(\alpha u_x)(x, y)|^2 \frac{1}{\alpha} \, dx \leq \frac{1}{C_\alpha(T)} \int_{a_1}^{b_1} |\partial_x (\alpha u_x)(x, y)|^2 \frac{1}{\alpha} \, dx,
$$

that is to say

$$
\int_{a_1}^{b_1} |u_x(x, y)|^2 \, dx \leq \frac{1}{C_\alpha(T)} \int_{a_1}^{b_1} \left\| \frac{\partial_x (\alpha u_x)}{\alpha} \right\|_{L_2}^2 \, dx.
$$

Thus, by integrating over $[a_2, b_2]$, we find

$$
\|u_x\|_{L_2}^2(t) \leq \frac{1}{C_\alpha(T)} \left\| \frac{\partial_x (\alpha u_x)}{\alpha} \right\|_{L_2}^2(t). \tag{31}
$$

We apply the same analysis for $u_y$ such that $0 = \int_{a_2}^{b_2} u_y(x, y) \, dy = \int_{a_2}^{b_2} (\alpha u_y)(x, y) \frac{1}{\alpha} \, dy$, which gives

$$
\|u_y\|_{L_2}^2(t) \leq \frac{1}{C_\alpha(T)} \left\| \frac{\partial_y (\alpha u_y)}{\alpha} \right\|_{L_2}^2(t). \tag{32}
$$

We obtain (29) with (30), (31) and (32).

To prove inequality (24), we firstly have to prove the following lemma:

**Lemma 6.5.** There exists a constant $K_\alpha(T) > 0$ depending on $T$ and $\alpha$ such that

$$
\forall t \geq 0, \quad \|q_2 - P_{\alpha=1,\alpha} P_{\alpha=0} q^0\|_{L_2(t)} \leq \| (1 - P_{\alpha=1,\alpha}) \circ P_{\alpha=0} q^0\|_{L_2(t)} \exp \left( -\frac{\alpha \min(\Delta x, \Delta y)}{2MK_\alpha(T)} t \right). \tag{33}
$$

Proof. Let us define $\hat{q} = q_2 - P_{\alpha=1,\alpha} P_{\alpha=0} q^0 =: (\hat{r}, \hat{u})^T$. The idea is to apply the inequality of Lemma 6.4 combined with the equality (21) in the proof of Lemma 5.2. For this, we firstly prove that $\hat{q}$ satisfies (18). Since $q_2$ satisfies (18), $\hat{q}$ satisfies (18) if and only if $P_{\alpha=1,\alpha} P_{\alpha=0} q^0$ satisfies (18). Since $\text{Im} P_{\alpha=1,\alpha} \subset \text{Ker} L_{\alpha=1,\alpha}$, we have...
\( L_{\kappa=1,\alpha} (P_{\kappa=1,\alpha} P_\alpha q^0) = 0 \) and then \( P_{\kappa=1,\alpha} P_\alpha q^0 \) satisfies (18). Then, \( \dot{q} \) is solution of (18) and by using (21), we obtain
\[
\frac{1}{2} \frac{d}{dt} \|\dot{q}\|^2_{L^2} (t) = -\frac{a_*}{2M} \left( \Delta \|\dot{r}\|^2_{L^2} + \Delta y \|\dot{\nu}_x\|^2_{L^2} (t) + \kappa \Delta x \left\| \frac{\partial_x (a_\nu_x)}{\alpha} \right\|^2_{L^2} (t) + \kappa \Delta y \left\| \frac{\partial_y (a_\nu_y)}{\alpha} \right\|^2_{L^2} (t) \right)
\]
\[
\leq -\frac{a_*}{2M} \min (\Delta x, \Delta y) \left( \left\| \nabla \dot{r}_x \right\|^2_{L^2} (t) + \left\| \frac{\partial_x (a_\nu_x)}{\alpha} \right\|^2_{L^2} (t) + \left\| \frac{\partial_y (a_\nu_y)}{\alpha} \right\|^2_{L^2} (t) \right)
\]
(34)
since \( \kappa = 1 \). Since \( P_{\kappa=1,\alpha} \dot{q} (t = 0) = P_{\kappa=1,\alpha} (q_0^2 - P_{\kappa=1,\alpha} P_\alpha q^0) = P_{\kappa=1,\alpha} P_\alpha q^0 - P_{\kappa=1,\alpha} \circ P_\alpha q^0 = 0 \) and since \( \text{Ker} \ P_{\kappa=1,\alpha} \) is invariant for Equation (18) (in the sense of (28)), we have \( \dot{q} (t \geq 0) \in \text{Ker} \ P_{\kappa=1,\alpha} \). Thus, we can apply Lemma 6.4 to \( \dot{q} \) and we obtain from (34)
\[
\frac{1}{2} \frac{d}{dt} \|\dot{q}\|^2_{L^2} (t) \leq -\frac{a_* \min (\Delta x, \Delta y)}{2MK_* (T)^2} \|\dot{q}\|^2_{L^2} (t).
\]
By applying the Grönwall’s lemma, we obtain (33) because \( \dot{q} (t = 0) = (1 - P_{\kappa=1,\alpha} \circ P_\alpha q^0) \).

Now, we are able to prove Theorem 6.2. By applying Lemma 6.5, we have for all \( t \geq 0 \):
\[
\| q_2 - P_\alpha q^0 \|^2_{L^2} (t) \geq \| P_\alpha q^0 - P_{\kappa=1,\alpha} P_\alpha q^0 \|^2_{L^2} (t) = \| q_2 - P_{\kappa=1,\alpha} P_\alpha q^0 \|^2_{L^2} (t)
\]
\[
\geq \| (1 - P_{\kappa=1,\alpha}) \circ P_\alpha q^0 \|^2_{L^2} \left( 1 - \exp \left( -\frac{a_* \min (\Delta x, \Delta y)}{2MK_* (T)^2} t \right) \right).
\]
By noting that \( 1 - \exp (-x/2) \geq x/3 \) for \( x \in [0, 1] \), we have
\[
\forall t \leq \frac{MK_* (T) t}{a_* \min (\Delta x, \Delta y)} : 1 - \exp \left( -\frac{a_* \min (\Delta x, \Delta y)}{2MK_* (T)^2} t \right) \geq \frac{a_* \min (\Delta x, \Delta y)}{3MK_* (T)^2} t.
\]
Thus, we have also
\[
\forall t \in \left[ \frac{MK_* (T)}{a_*}, \frac{MK_* (T)^2}{a_* \min (\Delta x, \Delta y)} \right] : 1 - \exp \left( -\frac{a_* \min (\Delta x, \Delta y)}{2MK_* (T)^2} t \right) \geq \frac{\min (\Delta x, \Delta y)}{3K_* (T)}
\]
when \( \min (\Delta x, \Delta y) \leq K_* (T) \). Moreover, we have
\[
\forall t \geq \frac{MK_* (T)^2}{a_* \min (\Delta x, \Delta y)} : 1 - \exp \left( -\frac{a_* \min (\Delta x, \Delta y)}{2MK_* (T)^2} t \right) \geq 1 - \frac{1}{e}
\]
Then, if \( \min (\Delta x, \Delta y) \leq K_* (T) \), we have
\[
\forall t \geq \frac{MK_* (T)}{a_*} : 1 - \exp \left( -\frac{a_* \min (\Delta x, \Delta y)}{2MK_* (T)^2} t \right) \geq \frac{\min (\Delta x, \Delta y)}{3K_* (T)}, 1 - \frac{1}{e} = \frac{\min (\Delta x, \Delta y)}{3K_* (T)}
\]
because \( \frac{1}{e} \leq 1 - \frac{1}{\sqrt{e}} \). Then, if \( \min (\Delta x, \Delta y) \leq K_* (T) \), we have
\[
\forall t \geq C_2 M : \| q_2 - P_\alpha q^0 \|^2_{L^2} \geq \| (1 - P_{\kappa=1,\alpha}) \circ P_\alpha q^0 \|^2_{L^2} \left( \frac{\min (\Delta x, \Delta y)}{3K_* (T)} \right) \geq C \min (\Delta x, \Delta y)
\]
with \( C_2 = \frac{K_* (T)}{a_*} \) and \( C = \frac{\| (1 - P_{\kappa=1,\alpha}) \circ P_\alpha q^0 \|^2_{L^2}}{3K_* (T)} \). In the sequel, we suppose that \( C \) is strictly positive, which is the case for all function \( q^0 \in L^2 (\Omega)^3 \) such that \( P_\alpha q^0 \notin L_{\kappa=1,\alpha} \). Moreover, since Equation (18) is dissipative when \( \kappa \geq 0 \) (see Lemma 5.2), we can write that
\[
C_1 M = \| q_1 \|^2_{L^2} (0) \geq \| q_1 \|^2_{L^2} (t).
\]
Let us now suppose that \( C_1 M = C \min (\Delta x, \Delta y) \). Then, by using (27) and (35), we find
\[
\forall t \geq C_2 M : \| q - P_\alpha q^0 \|^2_{L^2} (t) \geq \| q_2 - P_\alpha q^0 \|^2_{L^2} (t) - \| q_1 \|^2_{L^2} (t) \geq C \min (\Delta x, \Delta y) - C_1 M \geq 0.
\]
Let us now suppose that \( C_1 M \leq C_3 \min (\Delta x, \Delta y) \) with \( C = \frac{C_3}{2} \). This gives
\[
\forall t \geq C_2 M : \| q - P_\alpha q^0 \|^2_{L^2} (t) \geq C_3 \min (\Delta x, \Delta y)
\]
for any \( M \leq \frac{C_3}{C_1} \min (\Delta x, \Delta y) \). This concludes the proof of Theorem 6.2.
7 Low Mach and all Mach corrections for the Godunov scheme to be accurate at low Mach number on a cartesian mesh

Theorem 6.2 shows that the Godunov scheme is not accurate (in the sense of Definition 6.1) at low Mach number when $M \ll \min(\Delta x, \Delta y)$. We now prove that the Godunov scheme is accurate when $\max(\Delta x, \Delta y)$ is of the order of $M$. Of course, this condition on the mesh is too expensive for practical applications. To overcome this difficulty, we propose a low Mach correction which allows to recover the accuracy when $M \ll \min(\Delta x, \Delta y)$. At last, we propose an all Mach correction which allows to recover the accuracy at low Mach number when $M \ll \min(\Delta x, \Delta y)$ and the Godunov scheme when the Mach number is of order one (when the porosity is constant, we show in [3] that this all Mach correction may be more robust than the low Mach correction when it is applied in the linear case with linear convection and in the non-linear case (1)). These three points are detailed in the following theorem:

**Theorem 7.1.** Let $q(t, x)$ be the solution of (18) with the initial condition $q^0$. We have:

1) The Godunov scheme – obtained with $\kappa = 1$ in (17) – is accurate at low Mach number when

$$\max(\Delta x, \Delta y) = O(M).$$

More precisely:

$$\forall(C_0, C_1, C_2) \in (\mathbb{R}_+)^3, \ \exists C_3 > 0 \text{ such that }$$

$$\begin{cases} 
\Delta x \leq C_0 M, \\
\Delta y \leq C_0 M, \\
\|q^0 - P_\alpha q^0\|_{L^2_\alpha} = C_1 M
\end{cases}$$

$$\implies \forall t \in [0, C_2 M], \ |q - P_\alpha q^0|_{L^2_\alpha}(t) \leq C_3 M$$

where $C_3$ does not depend on $M, \Delta x$ and $\Delta y$.

2) The low Mach Godunov scheme – obtained with $\kappa = 0$ in (17) – is accurate at low Mach number. More precisely:

$$\forall C_1 \in \mathbb{R}_+^+, \ |q^0 - P_\alpha q^0|_{L^2_\alpha} = C_1 M \implies \forall t \geq 0, \ |q - P_\alpha q^0|_{L^2_\alpha}(t) \leq C_3 M.$$  \hspace{1cm} (37)

3) The all Mach Godunov scheme – obtained with $\kappa = \min(1, M)$ in (17) – is accurate at low Mach number. More precisely:

$$\forall(C_1, C_2) \in (\mathbb{R}_+)^2, \ \exists C_3 > 0 \text{ such that }$$

$$\|q^0 - P_\alpha q^0\|_{L^2_\alpha} = C_1 M$$

$$\implies \forall t \in [0, C_2 M], \ |q - P_\alpha q^0|_{L^2_\alpha}(t) \leq C_3 M$$

where $C_3$ does not depend on $M$.

**Proof.** By linearity, the solution $q(t, x)$ of (18) with the initial condition $q^0$ can be written as

$$q(t, x) = q_1(t, x) + q_2(t, x)$$

where $q_1$ is the solution of (25) and $q_2$ is the solution of (26). We have

$$\forall t \geq 0, \ |q - P_\alpha q^0|_{L^2_\alpha}(t) = |q_1 + q_2 - P_\alpha q^0|_{L^2_\alpha}(t) \leq |q_1|_{L^2_\alpha}(t) + |q_2 - P_\alpha q^0|_{L^2_\alpha}(t) \leq |q^0 - P_\alpha q^0|_{L^2_\alpha} + |q_2 - P_\alpha q^0|_{L^2_\alpha}(t)$$

because Equation (18) is dissipative when $\kappa \geq 0$ (see Lemma 5.2). Then, if $\|q^0 - P_\alpha q^0\|_{L^2_\alpha} = C_1 M$, we just have to study the function $t \mapsto |q_2 - P_\alpha q^0|_{L^2_\alpha}(t)$, where $q_2$ is the solution of (26). Since $P_\alpha q^0 \in E_\alpha = \text{Ker } L_\alpha$, we have $L_\alpha(P_\alpha q^0) = 0$ and

$$\partial_t (\alpha P_\alpha q^0) + \frac{L_\alpha}{M}(P_\alpha q^0) = 0,$$

13
which implies, by using (26), that
\[
\partial_t \left( \alpha (q_2 - P_\alpha q^0) \right) + \frac{L_\alpha}{M} (q_2 - P_\alpha q^0) = B_{\kappa, \alpha} (q_2 - P_\alpha q^0) + B_{\kappa, \alpha} (P_\alpha q^0).
\]  
(40)

By multiplying (40) with \((q_2 - P_\alpha q^0)\), by integrating over \(T\) and by using (13), we obtain
\[
\left( \frac{q_2 - P_\alpha q^0}{\alpha}, \partial_t \left( \frac{q_2 - P_\alpha q^0}{\alpha}, B_{\kappa, \alpha} (q_2 - P_\alpha q^0) \right) \right)_\alpha + \left( \frac{q_2 - P_\alpha q^0}{\alpha}, B_{\kappa, \alpha} (P_\alpha q^0) \right)_\alpha.
\]
Since (20) allows to write that \(\left( \frac{q_2 - P_\alpha q^0}{\alpha}, B_{\kappa, \alpha} (q_2 - P_\alpha q^0) \right)_\alpha \leq 0\), we obtain
\[
\frac{1}{2} \frac{d}{dt} \|q_2 - P_\alpha q^0\|_{L^2_\alpha}^2 \leq \left( \frac{q_2 - P_\alpha q^0}{\alpha}, B_{\kappa, \alpha} (P_\alpha q^0) \right)_\alpha \leq \left\| \frac{B_{\kappa, \alpha} (P_\alpha q^0)}{\alpha} \right\|_{L^2_\alpha} \cdot \|q_2 - P_\alpha q^0\|_{L^2_\alpha}(t)
\]
that is to say
\[
\frac{d}{dt} \|q_2 - P_\alpha q^0\|_{L^2_\alpha}^2 (t) \leq \left\| \frac{B_{\kappa, \alpha} (P_\alpha q^0)}{\alpha} \right\|_{L^2_\alpha}^2.
\]
(41)

Since \(\nabla (P_\alpha r^0) = 0\), we deduce from (20) that
\[
\left\| \frac{B_{\kappa, \alpha} (P_\alpha q^0)}{\alpha} \right\|_{L^2_\alpha} \leq \max \left( \left( \frac{a_x \Delta x}{2M}, \frac{a_y \Delta y}{2M} \right), \left( \left\| \partial_x \left( \frac{\alpha P_\alpha u_\alpha^0}{\alpha} \right) \right\|_{L^2_\alpha}, \left\| \partial_y \left( \frac{\alpha P_\alpha u_\alpha^0}{\alpha} \right) \right\|_{L^2_\alpha} \right) \right).  
\]
Thus, by using the fact that \(\|q_2 - P_\alpha q^0\|_{L^2_\alpha} (0) = 0\), we obtain by using (41)
\[
\forall t \in [0, C_M], \quad \|q_2 - P_\alpha q^0\|_{L^2_\alpha} (t) \leq C_2 M \max \left( \left( \frac{a_x \Delta x}{2M}, \frac{a_y \Delta y}{2M} \right), \left( \left\| \partial_x \left( \frac{\alpha P_\alpha u_\alpha^0}{\alpha} \right) \right\|_{L^2_\alpha}, \left\| \partial_y \left( \frac{\alpha P_\alpha u_\alpha^0}{\alpha} \right) \right\|_{L^2_\alpha} \right) \right).  
\]
where \(C_\alpha (P_\alpha q^0) := \left( \left\| \partial_x \left( \frac{\alpha P_\alpha u_\alpha^0}{\alpha} \right) \right\|_{L^2_\alpha} + \left\| \partial_y \left( \frac{\alpha P_\alpha u_\alpha^0}{\alpha} \right) \right\|_{L^2_\alpha} \right) \). Thus, when \(\|q^0 - P_\alpha q^0\|_{L^2_\alpha} = C_1 M\), by using (39), we obtain
\[
\forall t \in [0, C_M], \quad \|q - P_\alpha q^0\|_{L^2_\alpha} (t) \leq M \left( C_1 + C_2 C_\alpha (P_\alpha q^0) \frac{a_x}{2M} \max (\Delta x, \Delta y) \right).  
\]
(42)

Let us now suppose that \(\kappa = 1\). In that case, Inequality (42) becomes
\[
\forall t \in [0, C_M], \quad \|q - P_\alpha q^0\|_{L^2_\alpha} (t) \leq M \left( C_1 + C_2 C_\alpha (P_\alpha q^0) \frac{a_x}{2M} \max (\Delta x, \Delta y) \right)  
\]
which allows to obtain (36) with \(C_3 = C_1 + C_2 C_\alpha (P_\alpha q^0) \frac{a_x}{2M} \max \Delta x, \Delta y\). We now assume that \(\kappa = M\). In this case, (42) can be written as
\[
\forall t \in [0, C_M], \quad \|q - P_\alpha q^0\|_{L^2_\alpha} (t) \leq M \left( C_1 + C_2 C_\alpha (P_\alpha q^0) \frac{a_x}{M} \max (\Delta x, \Delta y) \right)  
\]
which allows to obtain (38) with \(C_3 = C_1 + C_2 C_\alpha (P_\alpha q^0) \frac{a_x}{2} \max (\Delta x, \Delta y)\). When \(\kappa = 0\), we have
\[
\left\| \frac{B_{\kappa=0, \alpha} (P_\alpha q^0)}{\alpha} \right\|_{L^2_\alpha} = 0.
\]
Then, we deduce from (41) that
\[
\frac{d}{dt} \|q_2 - P_\alpha q^0\|_{L^2_\alpha} (t) = 0
\]
which implies that \(\|q_2 - P_\alpha q^0\|_{L^2_\alpha} (t) = 0\) for any non-negative time since \(\|q_2 - P_\alpha q^0\|_{L^2_\alpha} (0) = 0\). As a consequence, we deduce from (39) that
\[
\forall t \geq 0, \quad \|q - P_\alpha q^0\|_{L^2_\alpha} (t) \leq \|q^0 - P_\alpha q^0\|_{L^2_\alpha}  
\]
which gives (37) since \(\|q^0 - P_\alpha q^0\|_{L^2_\alpha} = C_1 M\).
8 Numerical results

We illustrate Theorem 6.2 and Theorem 7.1 with an initial condition \( q^0 \). We choose an initial condition \( q^0 \) such that
\[
q^0_0 = Mq^0_1 + q^0_2 \quad \text{where} \quad q^0_1 \in E^\perp_\alpha, \quad \|q^0_1\|_{L^2_\alpha} = 1 \quad \text{and} \quad q^0_2 \in E_\alpha.
\]
The function \( q^0_1 := (r^0_1, u^0_1)^T \) is given by
\[
\begin{align*}
\begin{cases}
r^0_1(x, y) = \frac{\sin(2\pi x) \cos(2\pi y)}{a(x, y)}, \\
u^0_1 = \nabla \phi
\end{cases},
\end{align*}
\]
where
\[
\begin{align*}
\alpha(x, y) &= \frac{1}{2} + \frac{1}{4} \sin(\pi x) \sin(2\pi y), \\
\phi(x, y) &= \sin(2\pi x) \cos(2\pi y).
\end{align*}
\]
The functions \( \alpha, r_1 \) and \( \phi \) are defined at the cell center. The function \( q^0_2 := (r^0_2, u^0_2)^T \) is given by
\[
\begin{align*}
\begin{cases}
r^0_2 = 1, \\
u^0_2 = \nabla \times \psi
\end{cases},
\end{align*}
\]
where
\[
\begin{align*}
\psi(x, y) &= \frac{1}{\pi} \sin^2(\pi x) \sin^2(\pi y).
\end{align*}
\]
By construction, we have \( q^0_1 \in E^\perp_\alpha \) with \( \|q^0_1\|_{L^2_\alpha} = 1 \) and \( q^0_2 \in E_\alpha \). Moreover, we choose the parameters \( a_* = 1, \ M = 10^{-2} \) and \( \text{CFL} = 0.4 \) where \( \Delta t = \text{CFL} \times a_* \frac{\min(\Delta x, \Delta y)}{M} \). We compare the results obtained with the Godunov scheme (\( \kappa = 1 \)), the all Mach scheme (\( \kappa = M \)) and the low Mach scheme (\( \kappa = 0 \)).

In Figure 1, Figure 2 and Figure 3, we plot the norm of \( \alpha u \) in each cell at the initial time and at the final time \( t_{\text{final}} = M = 10^{-2} \). On a \( 30 \times 30 \) cartesian mesh, the solution given by the Godunov scheme (\( \kappa = 1 \)) is very diffused over time while the solution on a \( 300 \times 300 \) cartesian mesh seems to be close to the initial condition (see Figure 1 and Figure 2). These numerical results illustrate the inaccuracy of the Godunov scheme (\( \kappa = 1 \)) at low Mach number when \( M \ll \min(\Delta x, \Delta y) \) (see Theorem 6.2) and its good behaviour if we use a very fine mesh (i.e. such that \( \min(\Delta x, \Delta y) = O(M) \): see Point 1 of Theorem 7.1). Moreover, the low Mach Godunov scheme and the all Mach Godunov scheme allow to keep the accuracy at low Mach number even when \( M \ll \min(\Delta x, \Delta y) \) (see Points 2 and 3 of Theorem 7.1) since the numerical solutions given by these schemes are near the initial condition (see Figure 1 and Figure 3).

9 Conclusion

We proposed a low Mach correction and an all Mach correction for the Godunov scheme applied on a cartesian mesh to the linear wave equation with porosity. These corrections have been justified by studying the time behaviour of a solution of the first order modified equations associated to these schemes. It remains to justify these corrections in the discrete cartesian case. The triangular case is also important since we know that the Godunov scheme with a constant porosity is accurate at low Mach number on a triangular (or tetrahedral) mesh [7, 5]. These two points are studied in [2].
Figure 1: Norm of the velocity $\alpha u$ at initial time.

Figure 2: Norm of the velocity $\alpha u$ at final time $t_{\text{final}} = M = 10^{-2}$ with the Godunov scheme ($\kappa = 1$) on a $30 \times 30$ cartesian mesh (left picture) and on a $300 \times 300$ cartesian mesh (right picture). On the coarse mesh, the velocity field is very diffused over time while it seems to be close to the initial condition (see Figure 1) for a fine mesh. These numerical results illustrate the inaccuracy of the Godunov scheme ($\kappa = 1$) at low Mach number when $M \ll \min(\Delta x, \Delta y)$ (see Theorem 6.2) and its good behaviour if we use a very fine mesh i.e. such that $\max(\Delta x, \Delta y) = O(M)$ (see Point 1 of Theorem 7.1).

Figure 3: Norm of the velocity $\alpha u$ at final time $t_{\text{final}} = M = 10^{-2}$ with the low Mach Godunov scheme ($\kappa = 0$) and the all Mach Godunov scheme ($\kappa = M$) on a $30 \times 30$ cartesian mesh. The low Mach Godunov scheme ($\kappa = 0$) and the all Mach Godunov scheme ($\kappa = M$) allow to keep the accuracy at low Mach number even when $M \ll \min(\Delta x, \Delta y)$ (see Points 2 and 3 of Theorem 7.1) since the numerical solutions given by these schemes are near the initial condition (see Figure 1).
Appendix

Poincaré-Wirtinger inequality for weighted space

**Proposition.** Assume that $\Omega$ is an open convex bounded space in $\mathbb{R}^{d} \in \{1,2,3\}$ and that $\mu$ is a probabilistic measure on $\Omega$ such that $\mu$ and $\frac{1}{\mu}$ are in $L^\infty(\Omega)$. Then, we have:

$$\forall \phi \in H^1(\Omega) : \quad \int_{\Omega} |\phi(x) - \bar{\phi}|^2 \mu(x) dx \leq 2 \text{diam}(\Omega)^2 \|\mu\|_\infty \int_{\Omega} |\nabla \phi|^2 \mu(x) dx$$

(43)

where $\bar{\phi} := \int_{\Omega} \phi(x) \mu(x) dx$ and $\text{diam}(\Omega) := \sup_{(x,y) \in \Omega^2} |x - y|$.

**Proof.** The proof is done for $d \in \{1,2,3\}$. We have for all $(x,y) \in \Omega^2$

$$\phi(x) - \phi(y) = \int_{0}^{1} \nabla \phi((1-t)x + ty) \cdot (x-y) dt \Rightarrow \phi(x) - \bar{\phi} = \int_{0}^{1} \nabla \phi((1-t)x + ty) \cdot (x-y) dt \mu(y) dy$$

$$\Rightarrow (\phi(x) - \bar{\phi})^2 \leq \int_{0}^{1} \int_{0}^{1} \nabla \phi((1-t)x + ty) \cdot (x-y)^2 dt \mu(y) dy$$

$$\Rightarrow (\phi(x) - \bar{\phi})^2 \leq \int_{0}^{1} \int_{0}^{1} |\nabla \phi((1-t)x + ty)|^2 |x-y|^2 dt \mu(y) dy$$

with a Jensen inequality (with the function squared) and a Cauchy-Schwartz inequality. By multiplying by $\mu(x)$ and by integrating on $\Omega$, we find

$$\int_{\Omega} (\phi(x) - \bar{\phi})^2 \mu(x) dx \leq \int_{\Omega} \int_{0}^{1} |\nabla \phi((1-t)x + ty)|^2 |x-y|^2 dt \mu(y) dy \mu(x) dx$$

which implies that

$$\int_{\Omega} (\phi(x) - \bar{\phi})^2 \mu(x) dx \leq \text{diam}(\Omega)^2 \int_{\Omega} \int_{0}^{1} |\nabla \phi((1-t)x + ty)|^2 dt \mu(y) dy \mu(x) dx.$$  

We split the integral by integrating on $[0, \frac{1}{2}]$ and on $[\frac{1}{2}, 1]$. This gives

$$\int_{\Omega} (\phi(x) - \bar{\phi})^2 \mu(x) dx \leq \text{diam}(\Omega)^2 \int_{\Omega} \int_{0}^{\frac{1}{2}} \left( \int_{0}^{\frac{1}{2}} |\nabla \phi((1-t)x + ty)|^2 dt \right) \mu(y) dy \mu(x) dx$$

$$\leq \text{diam}(\Omega)^2 \|\mu\|_\infty \left( \int_{\Omega} \int_{0}^{\frac{1}{2}} \nabla \phi((1-t)x + ty) |\nabla \phi((1-t)x + ty)|^2 dt dx \mu(y) dy + \int_{\Omega} \int_{0}^{\frac{1}{2}} \nabla \phi((1-t)x + ty) |\nabla \phi((1-t)x + ty)|^2 dt dx \mu(x) dx \right)$$

$$= \text{diam}(\Omega)^2 \|\mu\|_\infty \left( \int_{\Omega} \int_{0}^{\frac{1}{2}} \omega(t,x) |\nabla \phi(z)|^2 \frac{dz}{1-t} dt \mu(y) dy + \int_{\Omega} \int_{0}^{\frac{1}{2}} \omega(t,x) |\nabla \phi(z)|^2 \frac{dz}{1-t} dt \mu(x) dx \right)$$

where $\omega(t,x)$ and $\omega(t,y)$ are included in $\Omega$. Thus, by replacing $\omega(t,x)$ and $\omega(t,y)$ with $\Omega$, and since $\frac{1}{1-t} \geq 1$ when $t \in [\frac{1}{2}, 1]$ and $\frac{1}{1-t} \geq 1$ when $t \in [0, \frac{1}{2}]$, we can write

$$\int_{\Omega} (\phi(x) - \bar{\phi})^2 \mu(x) dx \leq \text{diam}(\Omega)^2 \|\mu\|_\infty \int_{\Omega} |\nabla \phi(z)|^2 dz \left( \int_{\Omega} \int_{0}^{\frac{1}{2}} \frac{dz}{1-t} \mu(y) dy + \int_{\Omega} \int_{0}^{\frac{1}{2}} \frac{dz}{1-t} \mu(x) dx \right)$$

$$\leq \text{diam}(\Omega)^2 \|\mu\|_\infty \int_{\Omega} |\nabla \phi(z)|^2 dz \left( \int_{\Omega} \mu(y) dy + \int_{\Omega} \mu(x) dx \right)$$
which finally gives
\[
\int_\Omega \left( \phi(x) - \bar{\phi} \right)^2 \mu(x) \, dx \leq 2 \text{diam}(\Omega)^2 \|\mu\|_\infty \int_\Omega |\nabla \phi(z)|^2 \, dz.
\]

We obtain (43) by using the previous inequality and by noting that for all \( z \in \Omega \), we have 
\[
1 \leq \| \frac{1}{p} \|_\infty \mu(z).
\]
