†Guillaume Churlaud and Fabien Pitoiset have contributed equally to this work.

In addition to  $CD4^+$  regulatory T cells (Tregs),  $CD8^+$  suppressor T cells are emerging as an important subset of regulatory  $T$  cells. Diverse populations of  $CD8<sup>+</sup>T$  cells with suppressive activities have been described. Among them, a small population of  $CD8^+CD25^+FOXP3^+T$ cells is found both in mice and humans. In contrast to thymic-derived CD4+CD25+FOXP3<sup>+</sup> Tregs, their origin and their role in the pathophysiology of autoimmune diseases (AIDs) are less understood. We report here the number, phenotype, and function of CD8<sup>+</sup> Tregs cells in mice and humans, at the steady state and in response to low-dose interleukin-2 (IL-2).  $CD8<sup>+</sup>$  Tregs represent approximately 0.4 and 0.1% of peripheral blood T cells in healthy humans and mice, respectively. In mice, their frequencies are quite similar in lymph nodes (LNs) and the spleen, but two to threefold higher in Peyer patches and mesenteric LNs.  $CD8<sup>+</sup>$  Tregs express low levels of CD127.  $CD8<sup>+</sup>$  Tregs express more activation or proliferation markers such as CTLA-4, ICOS, and Ki-67 than other CD8<sup>+</sup> T cells. In vitro, they suppress effector T cell proliferation as well as or even better than CD4<sup>+</sup> Tregs. Owing to constitutive expression of CD25,  $CDB<sup>+</sup>$  Tregs are 20- to 40-fold more sensitive to in vitro IL-2 stimulation than CD8<sup>+</sup> effector T cells, but 2–4 times less than CD4<sup>+</sup> Tregs. Nevertheless, low-dose IL-2 dramatically expands and activates CD8<sup>+</sup> Tregs even more than CD4<sup>+</sup> Tregs, in mice and humans. Further studies are warranted to fully appreciate the clinical relevance of CD8<sup>+</sup> Tregs in AIDs and the efficacy of IL-2 treatment.

**Keywords: immunological tolerance, immunotherapy, autoimmunity,T cell biology, immune response**

#### **INTRODUCTION**

T cell development in the thymus comprises the positive selection of functional T cells capable of supporting adaptive immunity and the elimination of highly self-reactive T cells. The latter process is leaky and some autoreactive effector T cells (Teffs) escape into the periphery where they are regulated by peripheral tolerance mechanisms. In healthy individuals, multiple cell subsets with immunoregulatory properties, among  $CD4^+$  and  $CD8^+$  T cell or B cell populations, control these potentially harmful Teffs  $(1-3)$ .

The best characterized of such regulatory cell populations are the natural  $CD4+CD25+FOXP3+$  thymic-derived regulatory T cells (CD4<sup>+</sup> Tregs). Their major role in the maintenance of immunological self-tolerance and immune homeostasis (4, 5) is illustrated by the rapid development of autoimmune diseases (AIDs) in normal mice upon their depletion (4) and also by the occurrence of severe AID, allergy, and immunopathology in humans with a mutated FOXP3 gene  $(6)$ . CD4<sup>+</sup> Treg biology has dominated research on regulatory cells in AIDs. More recently, other regulatory cell populations have received attention, and notably  $CD8^+$  suppressor cells ( $CD8^+$  Tsups) for which evidence that they are involved in AIDs is growing  $(7-9)$ . However, CD8<sup>+</sup> Tsups are less well characterized than  $CD4^+$  Tregs.

 $CD8<sup>+</sup>$  Tsups are functionally defined populations of  $CD8<sup>+</sup>$ T cells endowed with immunosuppressive functions (10–14). Several subpopulations of  $CD8<sup>+</sup>$  Tsups have been described based on the expression of CD8αα, CD25, CD38, CD45RA, CD45RO, CD56, FOXP3, CXCR3, LAG-3, CD103, CD122, and/or HLA-G, as well as the absence of CD28 and CD127 (2, 7, 8, 15). The different CD8<sup>+</sup> Tsup subsets are multiply involved in the pathophysiology of different AIDs (16). Their suppressive activity in AIDs was first demonstrated in CD8-depleted mice, which were more susceptible to a second induction of experimental autoimmune encephalomyelitis (17). CD8-deficient mice were also more susceptible to relapse of autoimmune arthritis after immunization with self-antigens (18). In non-obese diabetic mice, antigenspecific CD8<sup>+</sup> Tsups were able to not only prevent but also reverse type 1 diabetes (15). Notably, in patients with systemic lupus erythematosus (19–21), inflammatory bowel disease (22), or multiple sclerosis (23–26) defective functions and/or reduced numbers of  $CD8<sup>+</sup>$  Tsups have been reported.  $CD8<sup>+</sup>$  Tsup biology is also less well known than that of  $CD4^+$  Tregs, due in part to their small numbers, which render functional studies difficult.

Only some CD8<sup>+</sup> Tsups express FOXP3, the master regulator of CD4<sup>+</sup> Treg differentiation and function, as well as CD25, and will be referred to here as  $CD8<sup>+</sup>$  Tregs. Many groups are now suggesting that FOXP3 expression might represent a good indicator of a bona fide suppressive function (7, 27–30). Notably, it was demonstrated in lupus-prone mice that silencing FOXP3 with siRNA abrogates the ability of  $CD8<sup>+</sup>$  Tregs to suppress anti-DNA antibodies (27, 29).

As  $CD8<sup>+</sup>$  Tregs express CD25, the question of their sensitivity to interleukin-2 (IL-2) is relevant. Stimulation with IL-2 is indeed crucial for CD4<sup>+</sup> Tregs. Mice deficient in IL-2 or in IL-2 receptor develop systemic AIDs that have been related to impaired development, survival, and function of  $CD4^+$  Treg cells  $(1, 31)$ . However, the lack of IL-2 signaling effects on  $CD8<sup>+</sup>$  Tregs has not been specifically evaluated in these models. Nevertheless, it is already known that, like  $CD4^+$  Tregs,  $CD8^+$  Tregs expand in response to IL-2 treatment, as we previously showed in a clinical trial using low-dose IL-2 in hepatitis C virus-induced vasculitis (32) and type 1 diabetes (33).

We sought to characterize CD8<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> Tregs in mice and humans, phenotypically and functionally, at steady state and under IL-2 stimulation *in vitro* and *in vivo*. We show here that CD8<sup>+</sup> Tregs are highly suppressive and responsive to IL-2. Our results warrant further study of these bona fide  $CD8<sup>+</sup>$  Tregs in AID pathophysiology and therapy.

#### **MATERIALS AND METHODS**

#### **HUMAN BLOOD SAMPLES**

Blood samples from healthy volunteers were obtained from the Etablissement français du sang (EFS) at the Pitié-Salpêtrière Hospital in Paris, France. Informed consent was obtained from each volunteer.

Blood samples from type 1 diabetes patients were obtained from the DF-IL2 trial (clinicaltrials.gov identifier NCT01353833). Patients were treated at the Centre d'Investigation Clinique (CIC)- Paris Est of la Pitié-Salpêtrière Hospital in Paris, France. Details about the clinical trial and the patients' clinical characteristics are described in Hartemann et al. (34). Written informed consent was obtained from all participants before enrolment in the study. The study was approved by the institutional review board of the Pitié-Salpêtrière Hospital, and was done in accordance with the Declaration of Helsinki and good clinical practice guidelines.

#### **MICE**

BALB/cJRj and C57Bl/6 mice were from Janvier. Transgenic C57Bl/6 FOXP3-GFP mice that express green fluorescent protein (GFP) in FOXP3<sup>+</sup> cells were kindly provided by Dr. Malissen of the Centre d'immunologie de Marseille Luminy (France). CD3 KO mice were from CDTA of Orléans (France). Animals were maintained in our animal facility under specific pathogenfree conditions in agreement with current European legislation on animal care, housing, and scientific experimentation. All procedures were approved by the Regional Ethics Committee on Animal Experimentation No. 5 of the Ile-de-France region (Ce5/2012/031).

#### **Preparation of tissue-infiltrating lymphocytes in mice**

Spleen, lymph nodes (LNs) (mesenteric LN, MLN; cervical LN, CLN; pancreatic LN, PaLN), and Peyer's patches (PP) were isolated

and dissociated in PBS 3% fetal calf serum (FCS). Pancreas was digested with collagenase/DNase solution in RPMI medium, and filtered as described (35). A Ficoll (Sigma-Aldrich) gradient was used to isolate tissue-infiltrating lymphocytes.

#### **Interleukin-2 treatment in mice**

Eight-week-old female BALB/c mice received intraperitoneal injections of 50,000 or 100,000 IU of recombinant human IL-2 (Proleukin, Novartis) or PBS daily for 5 days. Twenty-four hours after the last injection, blood was collected and analyzed by flow cytometry.

#### **FLOW CYTOMETRY**

#### **Analysis of cell surface and intracellular markers and FOXP3 expression in mice**

Fresh total cells from the respective tissues were directly stained with the following monoclonal antibodies (mAbs) at predetermined optimal dilutions for 20 min at 4°C: CD3-PE, CD8- Alexa700, CD4-HorizonV500, CD127-FITC, and CD25-PeCy7 (eBioscience). Intracellular detection of FOXP3 (FOXP3-E450, eBioscience), CTLA-4 (CTLA-4-APC, eBioscience), Ki-67 (Ki-67- FITC, BD Pharmingen), and Bcl-2 (Bcl-2-PE, BD Pharmingen) was performed on fixed and permeabilized cells using appropriate buffer (eBioscience) (incubation 30 min at 4°C). Cells were acquired on an LSR II flow cytometer (Becton Dickinson) and analyzed using FlowJo software (Tree Star, Inc.). Dead cells were excluded by forward/side scatter gating.

#### **Analysis of cell surface markers and FOXP3 expression in humans**

Direct*ex vivo* immunostaining was performed on 50µL of lithium heparinized fresh whole blood from healthy donors using the PerFix-nc kit (Beckman Coulter) according to the manufacturer's instructions. Briefly,  $5 \mu L$  of fixative reagent was added to the blood for 15 min at room temperature in the dark, before adding antibodies diluted in  $300 \mu L$  of permeabilizing reagent for 1h at room temperature in the dark. Staining was performed with FOXP3<sup>−</sup> AF647 (clone 259D), CD25-PE, CD127-PE-Cy7, CD8- Chrome Orange, CD4-Pacific Blue, CD3-FITC, CD103-APC, ICOS-FITC, CD122-FITC, and CCR7-PE mAbs, all from Beckman Coulter. CTLA-4-PeCy7 mAb was from Biolegend. Samples were acquired on a Navios cytometer (Beckman Coulter) and analyses were performed using Kaluza software (Beckman Coulter). Matched mouse isotype control antibodies were used.

Instrument settings (gain, compensation, and threshold) were set with machine software (Navios Software; Beckman Coulter) in conjunction with calibration beads (Flow-set beads, Cytocomp kit, and CYTO-TROL Control Cells). Machine reproducibility was verified with standardized beads (Flow-check).

In mice and in humans,  $CD4^+$  Tregs were defined as  $CD25^+$ FOXP3<sup>+</sup> cells among CD4<sup>+</sup> T cells, and effector CD4<sup>+</sup> T cells as FOXP3<sup>−</sup> cells among CD4<sup>+</sup> T cells. CD8<sup>+</sup> Tregs were defined as CD25+FOXP3<sup>+</sup> cells among CD8<sup>+</sup> T cells, and effector CD8<sup>+</sup> T cells as FOXP3<sup>−</sup> cells among CD8<sup>+</sup> T cells.

#### **Absolute numbers of CD8**<sup>+</sup> **Tregs and CD4**<sup>+</sup> **Tregs in peripheral blood**

Briefly, PBMC subsets  $(CD4^+$  Tregs,  $CD8^+$  Tregs) counts  $(cells/\mu L)$  were established from fresh blood samples using Flowcount fluorescents beads (Beckman Coulter) as internal standard (33).

#### **pSTAT5 staining procedure**

The pSTAT5 staining was assessed using PerFix EXPOSE reagents from Beckman Coulter as previously described (36). Briefly, fresh lithium heparinized whole blood was stained using anti-CD4, anti-CD25, anti-FOXP3, and PE-conjugated anti-phosphorylated STAT5 (Beckman Coulter) antibodies. Blood samples were stimulated with increasing hIL-2 (proleukin, Novartis) concentrations at 37°C for 10 min. Cell surface staining was then performed. Whole blood was incubated for 5 min (37°C, incubator). Samples were fixed for 10 min at room temperature in the dark, using  $50 \mu L$ of fixative reagent (PerFix EXPOSE). Aliquots were permeabilized using 1 mL of permeabilizing reagent (PerFix EXPOSE), and incubated for 5 min at 37°C. Samples were centrifuged at 300  $\times$  g for 5 min, and the supernatant was completely discarded by aspiration. Then, intracellular staining with a mixture of  $100 \mu L$  of staining reagent including PE-anti-pSTAT5 and AF647-anti-FOXP3 antibodies was performed for 30 min (room temperature) and cells were washed with 3 mL of washing buffer (PerFix EXPOSE). The supernatant was completely discarded by aspiration and  $300 \mu L$ of PBS was added.

### **IN VITRO SUPPRESSION ASSAY**

Four C57Bl/6 FOXP3-GFP mice were sacrificed, and spleen and LN were collected and dissociated in PBS 3% FCS. Cells were stained with CD3, CD4, CD8, and CD25 (as described above) and then sorted using a FACS ARIA cell sorter (Becton Dickinson).  $CD4^+GFP^-$  ( $CD4^+$  Teffs),  $CD4^+CD25^+GFP^+$  ( $CD4^+$ Tregs), and CD8+CD25+GFP<sup>+</sup> (CD8<sup>+</sup> Tregs) were collected. The purity of cell preparations exceeded  $97\%$ . CD4<sup>+</sup> Teffs were cultured in RPMI 1640 medium supplemented with 5% FCS, 2 mmol/L l-glutamine, 100 U/mg/mL penicillin/streptomycin at  $5 \times 10^4$  cells/well, and variable numbers of regulatory cells were added in the presence of  $7.5 \times 10^4$  total splenocytes from CD3 KO mice and anti-CD3 (final concentration 0.1 µg/mL, BioXell).

 $3H$ -thymidine  $(1 \mu Ci/well)$  incorporation was evaluated during the final 16 h of the 3-day culture.

### **STATISTICAL ANALYSES**

Statistical significance was evaluated using GraphPad Prism version 5.00 for Windows (GraphPad Software, San Diego, CA, USA, [http://www.graphpad.com\)](http://www.graphpad.com) and calculated using the paired *t*test, Mann–Whitney test (comparison of means, unpaired test, non-parametric test, two-tail *p* value), or one-way ANOVA test, with  $p < 0.05$  (\*) taken as statistical significance (\*\* $p < 0.01$ ,  $***p<0.001$ , NS, non-significant).

#### **RESULTS**

# **CHARACTERIZATION AND PHENOTYPE OF CD8**+**CD25**+**FOXP3**<sup>+</sup> **Tregs**

We measured the percentages and absolute numbers of  $CD8<sup>+</sup>$ Tregs and  $CD4^+$  Tregs in human blood and in blood and lymphoid organs from C57Bl/6 and BALB/c mice. A representative gating strategy for CD8+CD25+FOXP3<sup>+</sup> Treg immunophenotyping by flow cytometry in humans (**Figure 1A**) and in BALB/c mice (**Figure 1B**) is shown in **Figure 1**. In mice, CD4<sup>+</sup> Tregs and  $CD8<sup>+</sup>$  Tregs were solely defined by the co-expression of FOXP3

and CD25. In human and to a lesser extent in mouse,  $CD4^+$  Tregs and CD8<sup>+</sup> Tregs were also characterized by low levels of CD127 compared to Teffs (Figure S1 in Supplementary Material).

In peripheral blood mononuclear cells (PBMCs) from human healthy donors, the percentage of  $CD8<sup>+</sup>$  Tregs among  $CD8<sup>+</sup>$ T cells was variable and below 1% ( $0.38 \pm 0.26$ , mean  $\pm$  SD,  $n = 37$ ; **Figure 2A**). It is noteworthy that a wide range of values was observed (0.1–1%) with a quite heterogeneous distribution, since few individuals had markedly higher values (**Figure 2A**). In comparison, the percentage of  $CD4^+$  Tregs among  $CD4^+$  T cells in human blood was higher and less variable  $(8.3 \pm 1.6)$ (**Figure 2C**).

In mice, the percentages of  $CD8<sup>+</sup>$  Tregs among  $CD8<sup>+</sup>$  T cells were  $0.07 \pm 0.04$  and  $0.12 \pm 0.07\%$  in peripheral blood of C57Bl/6 and BALB/c (**Figure 2A**). Similar or slightly higher values were observed in spleen and CLN in both mouse strains. When MLN and PP were analyzed, two to threefold higher values were observed as compared with blood values, except for PP in BALB/c mice. In comparison, in these different lymphoid tissues, the percentages of CD4<sup>+</sup> Tregs among CD4<sup>+</sup> T cells were around 50-fold higher in both C57Bl/6 and BALB/c mice (**Figure 2C**).

These 50-fold differences in percentages of  $CD4<sup>+</sup>$  Tregs and  $CD8<sup>+</sup>$  Tregs were also observed when looking at absolute numbers (**Figures 2B,D**) in both human and mouse.

We compared the phenotype of mouse CD8<sup>+</sup> Tregs with that of other  $CD8<sup>+</sup>$  T cells and of  $CD4<sup>+</sup>$  T cells, focusing mainly on proteins associated with the regulatory function of  $CD4^+$  Tregs (**Figure 3**). Most  $CD8^+$  Tregs expressed CD103 (85.2  $\pm$  11.8%) and some were  $CD122^+$  (11.9  $\pm$  9.6%) with significantly higher levels compared with CD8<sup>+</sup> Teffs only for CD103 expression ( $p < 0.0001$ ). Approximately 36% of them were ICOS<sup>+</sup> and only 9% expressed more CTLA-4 than  $CD8^+$  Teffs ( $p < 0.0001$  and  $p = 0.0025$ , respectively). CD8<sup>+</sup> Tregs had a proliferation rate measured by expression of Ki-67 (19.8  $\pm$  11.7%) that was more than three times higher than that of  $CD8^+$  Teffs (6.6  $\pm$  2.0%, *p* < 0.0001), whereas anti-apoptotic Bcl-2 marker expression was the same in  $CD8<sup>+</sup>$  Tregs and  $CD8<sup>+</sup>$  Teffs. This phenotype was similar in  $CD4<sup>+</sup>$  Tregs, except for a lower expression of CD103, CD122, and ICOS (**Figure 3**).

A large fraction of human CD8<sup>+</sup> Tregs express CTLA-4  $(59 \pm 19\%)$  (Figure S2 in Supplementary Material) as do CD4<sup>+</sup> Tregs. In contrast, CD8<sup>+</sup> Tregs do not express any of the other markers we tested, i.e., CD103, CD122, ICOS, and CCR7 (data not shown).

#### **SUPPRESSIVE ACTIVITY OF CD4**<sup>+</sup> **Tregs AND CD8**<sup>+</sup> **Tregs**

We next evaluated the suppressive capacity of  $CD8<sup>+</sup>$  Tregs. For that purpose, we used C57Bl/6 FOXP3-GFP mice. In these knockin mice, GFP is expressed only in *FOXP3* positive cells and can thus be used as a marker for flow cytometry sorting of viable  $CD8<sup>+</sup> Tregs.  $CD8<sup>+</sup> Tregs$  (CD8<sup>+</sup> $CD25<sup>+</sup> GFP<sup>+</sup>$ ) and  $CD4<sup>+</sup> Tregs$$  $(CD4+CD25+GFP+$ ) were sorted and evaluated for their capacity to suppress CD4<sup>+</sup> Teffs (CD4+GFP<sup>−</sup> cells). CD8<sup>+</sup> Tregs appeared slightly more suppressive than CD4<sup>+</sup> Tregs (**Figure 4**). At a 1:1 Treg:Teff ratio, 95% of CD4<sup>+</sup> Teff suppression was observed with  $CD8<sup>+</sup>$  Tregs and 77% with  $CD4<sup>+</sup>$  Tregs. Similar differences were observed at a 1:2 ratio in the same experiment and similar results were also obtained with human  $CD8<sup>+</sup>$  Tregs (28).

#### **IN VITRO SENSITIVITY TO IL-2 OF CD4**<sup>+</sup> **Tregs AND CD8**<sup>+</sup> **Tregs**

As CD4<sup>+</sup> Tregs and CD8<sup>+</sup> Tregs constitutively express CD25, included in the high-affinity IL-2 receptor, we investigated their sensitivity to *in vitro* IL-2 activation. We evaluated the IL-2-induced phosphorylation of STAT5 proteins (pSTAT5) by flow cytometry (**Figure 5**).  $CD4^+$  Tregs are exquisitely sensitive to IL-2 activation, activated with doses 20- to 40-fold lower than those required to activate  $CD4^+$  Teffs. It is noteworthy that  $CD8^+$ Tregs had the same 20- to 40-fold higher sensitivity to IL-2 activation as  $CD8<sup>+</sup>$  Teffs, but were 2- to 4-fold less sensitive than  $CD4<sup>+</sup>$ Tregs (**Figure 5A**). At 1 IU/mL, the proportion of pSTAT5 positive cells was of 77.7  $\pm$  3.8% in CD4<sup>+</sup> Tregs, 29.1  $\pm$  5.2% in CD8<sup>+</sup> Tregs, but only  $2.9 \pm 0.5$  and  $1.2 \pm 0.3\%$  in CD4<sup>+</sup> and CD8<sup>+</sup> Teffs, respectively. At 10 IU/mL, these proportions were  $91.9 \pm 1.5\%$  for CD4<sup>+</sup> Tregs,  $46.0 \pm 6.0\%$  for CD8<sup>+</sup> Tregs, and only  $13.4 \pm 2.4\%$ for CD4<sup>+</sup> Teffs and  $4.7 \pm 1.7\%$  for CD8<sup>+</sup> Teffs. These differences in IL-2-induced activation in  $CD4^+$  Tregs and  $CD8^+$  Tregs can be correlated with twofold higher levels of CD25 basal expression in CD4<sup>+</sup> Tregs compared with CD8<sup>+</sup> Tregs (**Figure 5B**).

### **IN VIVO SENSITIVITY TO IL-2 OF CD4**<sup>+</sup> **Tregs AND CD8**<sup>+</sup> **Tregs**

We next assessed the dynamics of  $CD4^+$  Tregs and  $CD8^+$  Tregs under low-dose IL-2 treatment, which is known to expand and activate CD4<sup>+</sup> Tregs. Seven patients with type 1 diabetes received 3 MIU of IL-2/day for 5 days (34). This led to a significant increase of  $CD8^+$  Tregs, which reached  $6.7 \pm 4.3$ -fold at day 5 (**Figure 6A**). This  $CD8<sup>+</sup>$  Treg expansion was not sustained at day 15, i.e., 10 days after the last IL-2 injection. IL-2 had a less pronounced effect on CD4<sup>+</sup> Tregs, reaching a 1.8  $\pm$  0.7-fold expansion at day 5. Nevertheless, and unlike  $CD8<sup>+</sup>$  Tregs, this increase was sustained until day 15 (1.8  $\pm$  0.6-fold). Interestingly, CD25 mean fluorescence intensity (MFI) was increased both on  $CD8^+$  Tregs and  $CD4^+$ Tregs after 5-day IL-2 treatment (**Figure 6B**). This CD25 increase was slightly higher for CD4<sup>+</sup> Tregs than for CD8<sup>+</sup> Tregs (2.1  $\pm$  0.3 versus  $1.6 \pm 0.4$ ;  $p = 0.005$ ).

In BALB/c mice injected daily for 5 days with 50,000 or 100,000 IU of IL-2, we observed a similar dose-dependent increase of percentages of CD4<sup>+</sup> and CD8<sup>+</sup> Tregs in peripheral blood as compared with controls injected with PBS (**Figure 7A**). A

5-day course of 50,000 IU of IL-2 led to a  $1.5 \pm 0.3$ -fold increase of  $CD4^+$  Tregs and  $1.5 \pm 0.6$ -fold increase of  $CD8^+$  Tregs. At 100,000 IU/day, the increase was  $1.9 \pm 0.1$ -fold for CD4<sup>+</sup> Tregs and  $1.8 \pm 0.5$ -fold for CD8<sup>+</sup> Tregs. Similarly to the human study, we observed an IL-2 dose-dependent increase of CD25 expression in both CD4<sup>+</sup> Tregs and CD8<sup>+</sup> Tregs (**Figure 7A**). The fold increase of CD25 MFI induced by 50,000 or 100,000 IU of IL-2 was  $1.4 \pm 0.2$  or  $1.8 \pm 0.2$  in CD4<sup>+</sup> Tregs and  $1.3 \pm 0.4$  or  $1.8 \pm 0.5$ in CD8<sup>+</sup> Tregs, respectively. In contrast, FOXP3 expression levels were slightly increased only in  $CD4^+$  Tregs (1.1  $\pm$  0.1 both with 50,000 and 100,000 IU of IL-2). No significant differences in FOXP3 expression level were observed in  $CD8<sup>+</sup>$  Tregs at the two doses.

We also monitored some activation and proliferation markers in CD4<sup>+</sup> Tregs and CD8<sup>+</sup> Tregs after a 5-day course of 50,000 IU of IL-2. Interestingly, CD103, CTLA-4, ICOS, Ki-67, and Bcl-2 expression levels were increased after IL-2 treatment in CD4<sup>+</sup> Tregs but not in CD8<sup>+</sup> Tregs (**Figure 7B** and representative stainings in Figure S2 in Supplementary Material). These results highlight the specific biology of CD8<sup>+</sup> Tregs compared with conventional CD4<sup>+</sup> Tregs.

### **DISCUSSION AND CONCLUSION**

### **ON BONA FIDE CD8**<sup>+</sup> **Tregs**

CD8<sup>+</sup> Tsups are heterogeneous and often poorly characterized if not controversial cells in mice and humans. We focused our study on  $CD8^+CD25^+FOXP3^+$  T cells, which we call  $CD8^+$ Tregs, because they are identified based on the same markers as  $CD4^+$  Tregs.  $CD8^+$  Tregs are present at steady state at low levels both in human and mouse peripheral blood (about 0.4 and

0.1%, respectively). We previously reported lower percentages of  $CD8<sup>+</sup>$  Tregs in blood of normal volunteers  $(0.22 \pm 0.1\%)$  (28), but we were using a different flow cytometry staining strategy. Because we optimized our flow cytometry analyses (choice of antibodies, analyses of whole blood with Perfix-NC kit), we believe that our new values accurately reflect their percentages. Natural  $CD8^+CD25^+FOXP3^+$  T cells are also present at very low frequencies (between 0.3 and  $1.8\%$  in CD8<sup>+</sup> T cells) in blood, LNs, thymus, and spleen from naive non-human primates (37, 38).

We report here that  $CD8<sup>+</sup>$  Tregs, as  $CD4<sup>+</sup>$  Tregs, constitutively express CD25 and are sensitive to *in vitro* IL-2 activation, to which they respond by STAT5 phosphorylation. Like  $CD4^+$  Tregs,  $CD8^+$ Tregs also express markers associated with CD4<sup>+</sup> Treg suppressive activity such as ICOS (39), CD103 (40, 41), and CTLA-4 (42, 43) at higher levels than other  $CD8<sup>+</sup>$  T cells. It is of note that nearly 80% of  $CD8<sup>+</sup>$  Tregs are  $CD103<sup>+</sup>$ , a marker associated with suppressive function of  $CD8<sup>+</sup>$  T cells (21, 40, 44). This phenotype is associated with a high suppressive activity *in vitro* in classic functional assays. Similar suppressive activities of  $CD8<sup>+</sup>$  Tregs have also been reported in humans (28) and non-human primates (45). Altogether,  $CD8+FOXP3+CD25+T$  cells share phenotypic and functional characteristics with thymic  $CD4<sup>+</sup>$  Tregs and are thus bona fide CD8<sup>+</sup> Tregs, a designation that should be restricted to this population.

As for  $CD4^+$  Tregs, it seems that there could be a population of induced CD8<sup>+</sup> Tregs. CD8+Foxp3<sup>+</sup> can be induced *ex vivo* from CD8<sup>+</sup>Foxp3<sup>−</sup> cells after culture in the presence of IL-2 and TGF-beta, but are only mildly suppressive (45, 46). Following simian immunodeficiency virus (SIV) infection, these peripheral CD8+CD25+Foxp3<sup>+</sup> regulatory T cells are largely induced

**(CD8**<sup>+</sup> **Teffs) and with CD4**<sup>+</sup>**CD25**<sup>+</sup>**FOXP3**<sup>+</sup> **Tregs (CD4**<sup>+</sup> **Tregs) in female BALB/c mice**. Representative histograms showing expression of CD103,

percentages in the overall population are shown. Individual values and mean  $\pm$  SEM are shown. not only in blood but also in colorectal mucosa (37, 38). These

cells have a regulatory phenotype  $(CD25^+$ , CTLA-4<sup>+</sup>, CD28<sup>+</sup>, CD127−) (26, 28) with high proliferative capacities as 60% of induced  $CD8<sup>+</sup>$  Tregs are Ki-67<sup>+</sup>. They express low levels of granzyme B and perforin, suggesting that their suppression is not mediated by killing.

## **ON DIFFERENCES BETWEEN CD4**<sup>+</sup> **Tregs AND CD8**<sup>+</sup> **Tregs**

While  $CD8^+$  Tregs and  $CD4^+$  Tregs share functional suppressive activity, differences in their biology have been reported. IL-2 can bind the high-affinity trimeric IL-2 receptor (IL-2R) (CD25, CD122, and CD132) or the low-affinity dimeric IL-2R (CD122 and CD132) (47, 48). The trimeric IL-2R is constitutively expressed on  $CD4^+$  Tregs, but only transiently expressed on  $CD4^+$  and  $CD8^+$ T cells following T cell receptor (TCR) activation (47). We show here that CD8<sup>+</sup> Tregs constitutively express the trimeric IL-2R, but compared with  $CD4^+$  Tregs,  $CD8^+$  Tregs express fewer CD25 molecules on their cell surface. CD4<sup>+</sup> Tregs are two to fourfold more sensitive to IL-2 activation than  $CD8^+$  Tregs, although both  $CD4^+$ 

**FIGURE 5 | Foxp3**<sup>+</sup> **CD25high CD127low CD4**<sup>+</sup> **T cells (CD4**<sup>+</sup> **Tregs) and Foxp3**<sup>+</sup> **CD25high CD127low CD8**<sup>+</sup> **T cells (CD8**<sup>+</sup> **Tregs) responsiveness to IL-2 and their comparative CD25 cell surface expressions**. **(A)** Total fresh blood from healthy donors was ex vivo stimulated with different doses of IL-2 for 10 min, and STAT5 phosphorylation was measured on different T cell subsets.

Results are expressed in mean  $\pm$  SE,  $n = 7-22$ . Low-dose IL-2 has been defined as the dose inducing high STAT5 phosporylation on CD4+ Tregs but not on CD4<sup>+</sup> Teff. **(B)** Mean fluorescence intensity (MFI) of CD25 on CD4<sup>+</sup> Tregs and CD8<sup>+</sup> Tregs ( $n = 37$ ) from fresh unstimulated whole blood from healthy donors. Individual values and mean  $\pm$  SEM are shown.

and  $CD8<sup>+</sup>$  Tregs are equally 20 times more sensitive to IL-2 than their FOXP3<sup>−</sup> counterparts. However, despite these differences in favor of CD4<sup>+</sup> Tregs *in vitro*, we observed that the sensitivity of  $CD8<sup>+</sup>$  Tregs to IL-2 *in vivo* is higher than that of  $CD4<sup>+</sup>$  Tregs (**Figure 6A**), a so far unexplained observation. In agreement with our observations, a very large increase of  $CD8<sup>+</sup>$  Tregs, greater than that for  $CD4^+$  Tregs, has been observed in blood of non-human primates following IL-2 treatment (49) in a context of tuberculosis infection.

Upon IL-2 activation, CD25 up-regulation is lower for  $CD8<sup>+</sup>$ than for  $CD4^+$  Tregs. Also, after IL-2 treatment, activation markers such as CD103, CTLA-4, and ICOS, which are increased in CD4<sup>+</sup> Tregs, are not increased in  $CD8<sup>+</sup>$  Tregs, suggesting that IL-2 regulates  $CD8<sup>+</sup>$  Tregs differently than  $CD4<sup>+</sup>$  Tregs. Further studies are needed to clarify the molecular effects of IL-2 on CD8<sup>+</sup> Tregs.

Importantly, we showed that CD8<sup>+</sup> Tregs suppress *in vitro* effector T cell proliferation as well as or even better than CD4<sup>+</sup> Tregs. This experiment has been performed only in mice as for now the low number of bona fide  $CD8<sup>+</sup>$  Tregs in peripheral blood from human healthy donors does not allow to perform suppressive assays with these cells. However, we have already showed that non-manipulated human cord blood  $CD8<sup>+</sup>$  Tregs are suppressive (50). It has also been reported that  $CD8<sup>+</sup>$  Tregs from healthy non-human primates suppress as well as CD4<sup>+</sup> Tregs (45). Thus, we can assume that, even if  $CD8<sup>+</sup>$  Tregs are less numerous than  $CD4^+$  Tregs in peripheral blood of human healthy donors, their excellent suppressive activity makes them important cells to consider in the regulation of immune responses.

For now, it has previously shown by others and us that *in vivo* IL-2 expanded CD4<sup>+</sup> Tregs have better *in vitro* suppressive activities than non-expanded CD4<sup>+</sup> Tregs. It remains to evaluate whether this is also true for  $CD8<sup>+</sup>$  Tregs functions.

### **ON THE POSSIBLE ROLE OF CD8**<sup>+</sup> **Tregs**

Several mechanisms have been implicated in the suppressive activity of suppressive CD8<sup>+</sup> T cells, including direct lysis of target cells and secretion of immunosuppressive cytokines (14).

CTLA-4 has been shown to play a role in cell–cell contactdependent mechanisms of  $CD4^+$  Tregs and  $CD8^+$  Treg-mediated suppression (51). As  $CD4^+$  Tregs,  $CD8^+$  Tregs may impede the up-regulation of CD80 and CD86 on immature dendritic cells or down-modulate them on mature dendritic cells (42) via CTLA-4, thereby inhibiting activation of Teffs. Jebbawi et al. (50) described a similar natural  $CD8<sup>+</sup>$  Treg population from cord blood. This population expresses CTLA-4 and can secrete IL-10 and TGF-beta compared with CD8+CD25<sup>−</sup> T cells.

 $CD8<sup>+</sup>$  Tregs have also been implicated in the regulation of human AID, including inflammatory bowel disease (22). Eusebio et al. (52) showed also that asthma patients have fewer CD8<sup>+</sup>

Tregs in blood than healthy control subjects. Furthermore, FOXP3 mRNA levels of CD8<sup>+</sup> T cells were significantly decreased in patients with severe asthma compared with mild to moderate asthma and control patients. Thus, natural CD8<sup>+</sup> Tregs could play a major role in control of allergic inflammation.

In cancer, Chaput et al. (28) and Kiniwa et al. (53) demonstrated that  $CD8<sup>+</sup>$  Tregs from colorectal and prostate tumors have strong immunosuppressive properties, and may contribute to tumoral immune escape and disease progression.

As many groups have reported the presence of  $CD8<sup>+</sup>$  Tregs after induction either by a drug or by pathological conditions (AIDs, cancer, infection, allergy), it remains to be seen in these models whether they are induced by pathological or natural conditions. In any case, we demonstrate here that bona fide  $CD8<sup>+</sup>$  Tregs are present at steady state in mice and humans.

#### **CONCLUSION**

Many questions remain, especially about the origin and role of natural  $CD8<sup>+</sup>$  Tregs in health and disease. Their striking phenotypic similarities with  $CD4^+$  Tregs, robust suppressive activity *in vitro* and exquisite sensitivity to IL-2 warrant further studies to fully appreciate their clinical relevance in AIDs and inflammatory diseases, and in IL-2 treatment efficacy.

#### **ACKNOWLEDGMENTS**

This work was supported by French state funds managed by the ANR within the Investissements d'Avenir programme under reference ANR-11-IDEX-0004-02. The authors thank Beckman Coulter and especially Fabrice Malergue and Olivier Jaen (Beckman Coulter employees) for their technical support. PSTAT5-PE antibody was kindly provided by Beckman Coulter. The authors also thank Charlotte Pouchy (UPMC UMRS CR7 – INSERM U1135), Michèle Barbie (AP-HP), and Bruno Gouritin (UPMC CNRS UMR 7211) for their technical support in the suppression experiments.
