Abstract

A special case of a combinatorial theorem of De Bruijn and Erdős asserts that every noncollinear set of n points in the plane determines at least n distinct lines. Chen and Chvátal suggested a possible generalization of this assertion in metric spaces with appropriately defined lines. We prove this generalization in all metric spaces induced by connected chordal graphs.

1 Introduction

It is well known that

(i) *every noncollinear set of n points in the plane determines at least n distinct lines.*

As noted by Erdős [11], theorem (i) is a corollary of the Sylvester–Gallai theorem (asserting that, for every noncollinear set S of finitely many points in

the plane, some line goes through precisely two points of S); it is also a special case of a combinatorial theorem proved later by De Bruijn and Erdős [10].

Theorem (i) involves neither measurement of distances nor measurement of angles: the only notion employed here is incidence of points and lines. Such theorems are a part of *ordered geometry* [7], which is built around the ternary relation of *betweenness*: point b is said to lie between points a and c if b is an interior point of the line segment with endpoints a and c. It is customary to write $[abc]$ for the statement that b lies between a and c. In this notation, a *line* $\overline{uv}$ is defined — for any two distinct points u and v — as

$$\{u, v\} \;\cup\; \{p : [puv] \vee [upv] \vee [uvp]\}. \tag{1}$$

In terms of the Euclidean metric *dist*, we have

$$\begin{aligned}&[abc] \;\Leftrightarrow\\ &a, b, c \text{ are three distinct points and } dist(a,b) + dist(b,c) = dist(a,c).\end{aligned} \tag{2}$$

In an arbitrary metric space, equivalence (2) defines the ternary relation of *metric betweenness* introduced in [12] and further studied in [1, 3, 8]; in turn, (1) defines the line $\overline{uv}$ for any two distinct points u and v in the metric space. The resulting family of lines may have strange properties. For instance, a line can be a proper subset of another: in the metric space with points u, v, x, y, z and

$$\begin{aligned}dist(u,v) = dist(v,x) = dist(x,y) = dist(y,z) = dist(z,u) = 1,\\ dist(u,x) = dist(v,y) = dist(x,z) = dist(y,u) = dist(z,v) = 2,\end{aligned}$$

we have

$$\overline{vy} = \{v, x, y\} \quad \text{and} \quad \overline{xy} = \{v, x, y, z\}.$$

Chen [4] proved, using a definition of $\overline{uv}$ different from (1), that the Sylvester–Gallai theorem generalizes in the framework of metric spaces. Chen and Chvátal [5] suggested that theorem (i), too, might generalize in this framework:

(ii) *True or false? Every metric space on n points, where $n \geq 2$, either has at least n distinct lines or else has a line that consists of all n points.*

They proved that

- every metric space on n points either has at least $\lg n$ distinct lines or else has a line that consists of all n points

and noted that the lower bound $\lg n$ can be improved to $\lg n + \frac{1}{2}\lg\lg n + \frac{1}{2}\lg\frac{\pi}{2} - o(1)$.

Every connected undirected graph induces a metric space on its vertex set, where $dist(u, v)$ is defined as the smallest number of edges in a path from vertex u to vertex v. Chiniforooshan and Chvátal [6] proved that

- every metric space induced by a connected graph on n vertices either has $\Omega(n^{2/7})$ distinct lines or else has a line that consists of all n vertices;

we will prove that the answer to (ii) is 'true' for all metric spaces induced by connected chordal graphs.

Theorem 1. *Every metric space induced by a connected chordal graph on n vertices, where $n \geq 2$, either has at least n distinct lines or else has a line that consists of all n vertices.*

For graph-theoretic terminology, we refer the reader to Bondy and Murty[2].

2 The proof

Given an undirected graph, let us write $[abc]$ to mean that a, b, c are three distinct vertices such that $dist(a, b) + dist(b, c) = dist(a, c)$; this is equivalent to saying that b is an interior vertex of a shortest path from a to c.

Lemma 1. *Let s, x, y be vertices in a finite chordal graph such that $[sxy]$. If $\overline{sx} = \overline{sy}$, then x is a cut vertex separating s and y.*

Proof. The set of all vertices u such that $dist(s, u) = dist(s, x)$ separates s and y. Among all its subsets that separate s and y, choose a minimal one and call it C. Since x is an interior vertex of a shortest path from s to y, it belongs to C. To prove that C includes no other vertex, assume, to the contrary, that C includes a vertex u other than x.

Our graph with C removed has distinct connected components S and Y such that $s \in S$ and $y \in Y$; the minimality of C guarantees that each of its vertices has at least one neighbour in S and at least one neighbour in Y. Since each of u and x has at least one neighbour in S, there is a path from u to x with at least one interior vertex and with all interior vertices in S. Let P be a shortest such path; note that P has no chords except possibly the chord ux. Similarly, there is a path Q from u to x with at least one interior vertex, and with all interior vertices in Y, that has no chords except possibly the chord ux. The union of P and Q is a cycle of length at least four; since this cycle must have a chord, vertices u and x must be adjacent. In turn, the union of Q and ux is a chordless cycle, and so Q has precisely two edges. This means that some vertex v in Y is adjacent to both u and x.

Write $i = dist(s,x)$ and $j = dist(x,y)$. Since all vertices t with $dist(s,t) < i$ belong to S and since v has no neighbours in S, we must have $dist(s,v) > i$; since $dist(x,v) = 1$, we conclude that $dist(s,v) = i+1$ and that $v \in \overline{sx}$. Since $\overline{sx} = \overline{sy}$, it follows that $v \in \overline{sy}$. Since $dist(v,x) = 1$ and $dist(x,y) = j$, we have $dist(v,y) \leq j+1$. From $dist(s,v) = i+1$, $dist(s,y) = i+j$, $dist(v,y) \leq j+1$, $i \geq 1$, $j \geq 1$, and $v \in \overline{sy}$, we deduce that $dist(v,y) = j-1$.

Since $dist(u,v) = 1$, it follows that $dist(u,y) \leq j$; since $dist(s,u) = i$ and $dist(s,y) = i+j$, we conclude that $dist(u,y) = j$ and $u \in \overline{sy}$. Since $dist(s,u) = i$, $dist(s,x) = i$, and $dist(u,x) = 1$, we have $u \notin \overline{sx}$. But then $\overline{sx} \neq \overline{sy}$, a contradiction. □

A vertex of a graph is called *simplicial* if its neighbours are pairwise adjacent.

Lemma 2. *Let s, x, y be three distinct vertices in a finite connected chordal graph. If s is simplicial and $\overline{sx} = \overline{sy}$, then $\overline{xy}$ consists of all the vertices of the graph.*

Proof. Since $\overline{sx} = \overline{sy}$, we have $y \in \overline{sx}$, and so $[ysx]$ or $[syx]$ or $[sxy]$; since s is simplicial, $[ysx]$ is excluded; switching x and y if necessary, we may assume that $[sxy]$. Given an arbitrary vertex u, we have to prove that $u \in \overline{xy}$. Let P be a shortest path from s to u and let Q be a shortest path from u to y. Lemma 1 guarantees that x is a cut vertex separating s and y, and so the concatenation of P and Q must pass through x. This means that $[sxu]$ or $[uxy]$ (or both). If $[uxy]$, then $u \in \overline{xy}$; to complete the proof, we may assume that $[sxu]$, and so $u \in \overline{sx}$.

Since $\overline{sx} = \overline{sy}$, we have $[usy]$ or $[suy]$ or $[syu]$; since s is simplicial, $[usy]$ is excluded. If $[suy]$, then $[sxu]$ implies $[xuy]$; if $[syu]$, then $[sxy]$ implies $[xyu]$; in either case, $u \in \overline{xy}$. □

Proof of Theorem 1. Consider a connected chordal graph on n vertices where $n \geq 2$. By a theorem of Dirac [9], this graph has at least two simplicial vertices; choose one of them and call it s. We may assume that the lines $\overline{sz}$ with $z \neq s$ are pairwise distinct (else some line consists of all n vertices by Lemma 2). Since the graph is connected and has at least two vertices, s has at least one neighbour; choose one and call it u. If u is the only neighbour of s, then every path from s to another vertex must pass through u, and so $\overline{su}$ consists of all n vertices. If s has a neighbour v other than u, then line $\overline{uv}$ is distinct from all of the $n-1$ lines $\overline{sz}$ with $z \neq s$: since s, u, v are pairwise adjacent, we have $s \notin \overline{uv}$. □

3 Related theorems

In Theorem 1, 'connected chordal graph' can be replaced by 'connected bipartite graph':

- every metric space induced by a connected bipartite graph on n vertices, where $n \geq 2$, has a line that consists of all n vertices.

In fact, $\overline{xy}$ consists of all n vertices whenever x and y are adjacent. To prove this, consider an arbitrary vertex u. Since the graph is bipartite, $dist(u, x)$ and $dist(u, y)$ have distinct parities; since $dist(x, y) = 1$, they differ by at most one. We conclude that $dist(u, x)$ and $dist(u, y)$ differ by precisely one, and so $u \in \overline{xy}$.

In Theorem 1, 'connected chordal graph' can be also replaced by 'sufficiently large graph of diameter two': Chiniforooshan and Chvátal [6] proved that

- every metric space on n points where each nonzero distance equals 1 or 2 has $\Omega(n^{4/3})$ distinct lines and this bound is tight.

Acknowledgment

The work whose results are reported here began at a workshop held at Concordia University in June 2011. We are grateful to the Canada Research Chairs program for its generous support of this workshop. We also thank Luc Devroye, François Genest, and Mark Goldsmith for their participation in the workshop and for stimulating conversations.
