Abstract

Stabilization of a class of underactuated vehicles with uncertain measurements of the position tracking error is addressed. Nonlinear feedback laws ensuring semi-global stability for a large class of uncertainties on these measurements are derived based on properties of saturated controls. Practical relevance of the proposed results is illustrated by two application examples for Vertical Take-Off and Landing aerial vehicles equipped with a mono-camera sensor: point stabilization in front of a planar target and visual way-points navigation based on interpolation of homography measures.

Keywords: Underactuated vehicle, aerial vehicle, stability, robustness, measurement uncertainties

1. Introduction

Underactuated vehicles have long been a source of inspiration for nonlinear control theory. Recent applications with aerial or underwater vehicles have renewed the interest on this topic. This study is motivated by applications with VTOL UAVs (i.e. Vertical Take-Off and Landing Unmanned Aerial Vehicles) but it is relevant to any underactuated vehicle that can be modeled as a rigid body with a body fixed thrust control force and full torque control (so-called "thrust propelled vehicles" Hua et al. (2009)). Stabilization of the vehicle's pose (i.e. position and orientation) is an important issue in this context. Large stability domains are needed for small vehicles due to their sensitivity to perturbations (wind, sea currents, etc), and several nonlinear control designs have been proposed to address this issue (see, e.g., Hauser et al. (1992); Isidori et al. (2003); Pflimlin et al. (2007); Hua et al. (2009)). Good robustness properties of the closed-loop system is at least as important in practice. Robustness to external perturbations (e.g. wind effects for aerial vehicles or currents for underwater vehicles) has been addressed in Pflimlin et al. (2007); Marconi and Naldi (2007); Aguiar and Pascoal (2007); Hua et al. (2009). Robustness to parameter uncertainties (mass, inertia, etc) has been considered e.g. in Aguiar and Pascoal (2007). Robustness to input disturbances has been considered in Aguiar et al. (2007). This paper concerns robustness w.r.t. (with respect to) uncertainties on the measurement model.

Motion capture systems provide high-quality pose measurements that can yield impressive performance for small aerial vehicles Lupashin et al. (2010); Mellinger et al. (2012). Alternatively, ground based passive visual markers have been used to

estimate onboard the pose as in Masselli and Zell (2012). For most applications, however, motion capture systems or ground based localization systems cannot be used and localization must rely exclusively on embarked sensors. Good orientation estimates can be obtained with embarked IMUs (Inertial Measurement Units). Estimation of the vehicle's position/velocity is more challenging. GPS may be used to this purpose but it is not always available. Furthermore, in many applications (e.g., inspection) a measurement of the *relative* position of the vehicle w.r.t. its environment is needed, rather than an absolute position measurement (GPS-like). The former is best obtained from embarked exteroceptive sensors (cameras, lasers, etc). With such sensors, however, the relation between the output function (i.e. measurement) and the relative position error is seldom known precisely. Uncertainties may come from calibration errors, lack of depth information with mono-camera sensors, uncertainties on the environment structure, etc... This leads to the control problem addressed in this paper: *Given a class of uncertainties on the position measurements, can one design feedback control laws that guarantee stability of the system for any position measurement in this class?*

To our knowledge this problem has only been addressed in very specific cases, like when uncertainties reduce to a positive scale factor on the position vector Metni et al. (2004); Le Bras et al. (2010). The results here proposed address a much larger class of uncertainties. They make use of properties of saturated controls. There is a large literature on this topic, especially for linear systems (see, e.g., Teel (1991); He et al. (2005)). In those works, it is assumed that the system's dynamics and state are perfectly known. Saturated controls have also been used for UAVs in order to ensure some type of robustness property, e.g., Teel (1996) and L6pez-Araujo et al. (2010) for robustness w.r.t. input saturation, Marconi and Naldi (2007), Hua et al. (2009), and L6pez-Araujo et al. (2010) for robustness w.r.t. unmodelled

dynamics. We show that saturated controls can be instrumental in ensuring robustness properties w.r.t. *measurement errors*. More precisely, we propose nonlinear feedback laws that ensure semi-global stability of the pose tracking error for a large class of uncertainties on the position measurement. These results are reminiscent of *Robust Stability* results for linear systems (Doyle et al., 1992, Ch. 4), where the objective is to guarantee stability for a family of plants that satisfy some uncertainty bound w.r.t. a nominal system. Two application scenarios are addressed. In the first one we assume that velocity measurements are available, e.g., a GPS provides these measurements and an exteroceptive sensor (e.g., camera) provides position measurements w.r.t. the environment. In the second scenario no velocity measurement is available, i.e., "GPS-denied" environment. Note that position control of UAVs without velocity measurements has already been addressed Abdessameud and Tayebi (2010), but position was assumed to be perfectly known. Finally, let us remark that a preliminary version of this paper was presented in de Plinval et al. (2012).

The results here proposed are illustrated by visual servoing applications with mono-camera measurements. This type of application has been considered in several works (see, e.g., Pebrianti et al. (2010); Saripalli et al. (2003) and additional references in Section 6) usually with a camera pointing downward and observing a flat and horizontal ground, and under the assumption that altitude is measured independently. Our results provide stability guarantees for much more general application scenarios.

The paper is organized as follows. Background and problem statement are presented in Section 2. A preliminary result is provided in Section 3 for the *fully actuated* case. The main results on the *underactuated* case are provided in Sections 4 and 5: in Section 4 we assume that linear velocity measurements are available; in Section 5 such measurements are not available. Application to visual servoing is considered in Section 6, with simulation results given in Section 7. Proofs are given in the Appendix.

2. Background and problem statement

The $n \times n$ identity matrix is denoted as I_n . The transpose of a matrix M is denoted as M^T . For any square matrix M , $M_s := \frac{M+M^T}{2}$ and $M_a := \frac{M-M^T}{2}$ respectively denote the symmetric and antisymmetric part of M . The maximum singular value of a matrix M is denoted as $|M|$ and when M is a matrix-valued time-function, $|M|_s := \sup_t |M(t)|$. Given a matrix-valued time-function $M : t \mapsto M(t) \in \mathbb{R}^{n \times n}$ with $M(t) \geq 0 \forall t$, we define $|M|_i := \sup_{\alpha I \leq M(t) \forall t} \alpha$. Note that $|M|_i = |M_s|_i$. Given a smooth function f defined on an open set of \mathbb{R} , its derivative is denoted as f' . Throughout the paper, *AS*, *GAS*, and *LES* stand for *Asymptotically Stable*, *Globally Asymptotically Stable*, and *Locally Exponentially Stable* respectively. *CD* stands for *Convergence Domain*.

Definition 1 Given $\delta := [\delta_m; \delta_M]$ with $0 < \delta_m < \delta_M$, $\text{sat}_\delta : \mathbb{R}^n \rightarrow \mathbb{R}^n$ is called a saturation function if:

- i) There exists a class C^1 function $s_\delta : \mathbb{R}^+ \rightarrow \mathbb{R}^+$ such that $\text{sat}_\delta(x) = s_\delta(|x|^2)x$ for all $x \in \mathbb{R}^n$;
- ii) The function defined on \mathbb{R}^+ by $\tau \mapsto s_\delta(\tau^2)\tau$ is non-decreasing, upper-bounded by δ_M , and is equal to the identity function on $[0, \delta_m]$;
- iii) $s'_\delta(\tau) \leq 0$ for all τ .

From i) sat_δ is fully defined from the associated function s_δ . From i)–ii) saturation functions in the sense of Def. 1 inherit the classical properties of a saturation function: sat_δ is upper-bounded in norm by δ_M and $\text{sat}_\delta(x) = x$ for $|x| \leq \delta_m$ (because $s_\delta(\tau^2)\tau = \tau$ for $\tau \in [0, \delta_m]$). Also,

$$\begin{aligned} s_\delta(\tau) &\leq 1, \quad \forall \tau \in \mathbb{R}^+ \\ \tau s_\delta(\tau) &\rightarrow +\infty \quad \text{when} \quad \tau \rightarrow +\infty \end{aligned} \quad (1)$$

where the first relation follows from ii) and iii) and the second relation from ii). Then, ii) implies that the derivative of the function $\tau \mapsto s_\delta(\tau^2)\tau$ is non-negative. This property and iii) imply that $2\tau|s'_\delta(\tau)| \leq s_\delta(\tau) \forall \tau \in \mathbb{R}^+$. Thus, from (1),

$$C_\delta := \sup_{\tau \in \mathbb{R}^+} (s_\delta(\tau) + 2\tau|s'_\delta(\tau)|) \leq 2 < +\infty \quad (2)$$

An example of a function s_δ is given by

$$s_\delta(\tau) := \begin{cases} 1 & \text{if } \tau \leq \delta_m^2 \\ \frac{\delta_M}{\sqrt{\tau}} - \frac{(\delta_M - \delta_m)^2}{\sqrt{\tau}(\sqrt{\tau} + \delta_M - 2\delta_m)} & \text{if } \tau > \delta_m^2 \end{cases} \quad (3)$$

2.1. Dynamics of thrust-propelled underactuated vehicles

We focus on the class of so-called "thrust-propelled underactuated vehicles" Hua et al. (2009), i.e., rigid bodies moving in 3D-space under the action of one body-fixed force control and full torque control. This class contains most VTOL UAVs (quadrotors, ducted-fans, etc). The dynamics of these systems is described by the following equations, expressed in a "North-East-Down" (NED) frame:

$$\begin{cases} \dot{p} &= -uRe_3 + ge_3 \\ \dot{R} &= RS(\omega) \\ J\dot{\omega} &= J\omega \times \omega + \Gamma \end{cases} \quad (4)$$

with p the position vector of the vehicle's center of mass, expressed in a reference (inertial) frame, R the rotation matrix from the body frame to the reference frame, ω the angular velocity vector expressed in the body frame, $S(\cdot)$ the matrix-valued function associated with the cross product, i.e. $S(x)y = x \times y$, $\forall x, y \in \mathbb{R}^3$, u the normalized thrust input, i.e. $u = \frac{T}{m}$ where m is the mass and T the thrust input, $e_3 = (0, 0, 1)^T$, J the inertia matrix, Γ the torque vector, and g the gravity constant. In this paper we mainly focus on the system

$$\begin{cases} \dot{p} &= -uRe_3 + ge_3 \\ \dot{R} &= RS(\omega) \end{cases} \quad (5)$$

with u and ω as control inputs, i.e., considering ω instead of Γ as orientation control. Extension of the paper's results to System (4) is discussed in Section 4.

2.2. Problem statement

The main objective of this paper is to investigate the stabilization of p to a reference trajectory p_r from some relative position measurements of the following form:

$$\tilde{\sigma}(t) := R(t)^T M(t) \tilde{p}(t) \quad (6)$$

with $M(t)$ an unknown matrix and $\tilde{p} := p - p_r$ the position error. In other words $\tilde{\sigma}$ provides information on the position error in body frame and $M(t)$ accounts for measurements uncertainties. Measurements $\tilde{\sigma}$ are typically obtained from embarked exteroceptive sensors (cameras, lasers, etc). Examples are provided in Section 6. Due to the system's underactuation, stabilization of p to p_r fixes two degrees of freedom on the vehicle's orientation. There remains a degree of freedom (yaw angle). Its control is not addressed here since it does not affect the position control.

Let us introduce some assumptions. The first one is made throughout the paper. The other ones concern particular cases.

A1: $M(t) > 0 \forall t$, $|M|_i > 0$, $|M|_s < +\infty$, $|\dot{M}|_s < +\infty$, and there exists a constant scalar $|\dot{p}_r|_s$ such that:

$$\forall t, \quad |\dot{p}_r(t)| \leq |\dot{p}_r|_s \quad (7)$$

A2: M is a constant function.

A3: $\ddot{p}_r = 0$ and $|\dot{p}_r| < g$.

A4: p_r is a constant vector and M_s and M_a commute.

3. A preliminary result

Before addressing the control of underactuated systems we consider a fully actuated system modelled by:

$$\ddot{p} = -Ru \quad (8)$$

where $u \in \mathbb{R}^3$ denotes the body-fixed thrust input and R satisfies the third kinematic relation in (5). We assume that the following measurements are available:

$$\tilde{\sigma}, v := R^T \dot{p} \quad (9)$$

with $\tilde{\sigma}$ defined by (6) and v the linear velocity in body frame. A reference trajectory is defined by:

$$p_r, v_r := R^T \dot{p}_r, a_r := R^T \ddot{p}_r \quad (10)$$

and the associated tracking error by:

$$\tilde{p} := p - p_r, \tilde{v} := v - v_r \quad (11)$$

Proposition 1 Let $\text{sat}_{\delta}, \overline{\text{sat}}_{\delta}$ denote two \mathbb{R}^3 -valued saturation functions with associated functions $s_{\delta}, \overline{s}_{\delta}$. Consider control gains $k_1, k_2 > 0$ such that

$$\begin{cases} k_2 |M|_i > k_1 |M_a|_s \max \{C_{\delta} |M|_s, |M_a|_s\} \\ k_2 \overline{\delta}_m > k_1 \delta_M \end{cases} \quad (12)$$

and define the control law

$$u := k_1 \text{sat}_{\delta}(\tilde{\sigma}) + k_2 \overline{\text{sat}}_{\delta}(\tilde{v}) - a_r \quad (13)$$

Then,

i) if **A1** and **A2** hold, then $(p, \dot{p}) = (p_r, \dot{p}_r)$ is a (uniformly) GAS and LES equilibrium trajectory for the closed-loop system (8)-(13).

ii) if **A1** holds then, for any $\rho > 0$, there exists $\vartheta > 0$ such that, for any M with $|\dot{M}|_s < \vartheta$, $(p, \dot{p}) = (p_r, \dot{p}_r)$ is a (uniformly) AS and LES equilibrium trajectory for the closed-loop system (8)-(13) with CD containing $\mathcal{A}_{\rho} := \{(p, \dot{p})(0) : |(\tilde{p}(0), \tilde{v}(0))| \leq \rho\}$, with $|(\tilde{p}, \tilde{v})| := \sqrt{|\tilde{p}|^2 + |\tilde{v}|^2}$.

Proposition 1 provides bounded feedback laws that ensure global (or semi-global) stability in the presence of uncertain measurements for System (8). Condition (12) can be used to specify admissible control gains given upper bounds on the uncertainties (the norm of M and of its skew-symmetric part M_a). This kind of result is very similar to classical Robust Stability theory for linear systems (Doyle et al., 1992, Ch. 4), Doyle and Stein (1981), Chen and Desoer (1982), where the objective is to guarantee stability for a set of plants that satisfy some uncertainty bound w.r.t. a nominal system. In our case, uncertainty corresponds to the difference between M and the identity matrix. If the uncertainty is small (which implies in particular that M_a is close to the zero matrix and $|M|_i \approx 1$), then Condition (12) puts little constraints on the control gains. If M_a is large, however, large values of k_2 are needed. In summary, Proposition 1 can provide stability guarantees given an a priori bound on uncertainties. Note also that when M is constant, global asymptotic stability can be obtained while only semi-global asymptotic stability is obtained when M varies with time (Case ii)).

4. Underactuated case with velocity measurements

Let us consider the control system (5), and assume that the following measurements are available:

$$\tilde{\sigma}, \gamma := gR^T e_3, v, \omega \quad (14)$$

Compared to the fully actuated case, there are two additional measurements, i.e. γ and ω . The latter is typically obtained from the gyrometers of an IMU, while the former is obtained by fusing accelerometer and gyrometer measurements (see, e.g. Mahony et al. (2012)). Let $q := Re_3$ denote the thrust direction, so that the first equality in (5) can also be written as

$$\ddot{p} = -uq + ge_3 = R(-ue_3 + \gamma) \quad (15)$$

If **A3** is satisfied then, along the reference position trajectory p_r the thrust direction is well defined (this is no longer true if $\ddot{p}_r = ge_3$ since any thrust direction q is solution to (15) for $u = 0$). More precisely, assuming that u is positive, this reference thrust direction is

$$q_r := \frac{ge_3 - \ddot{p}_r}{|ge_3 - \ddot{p}_r|} \quad (16)$$

Proposition 2 Let $\text{sat}_{\delta}, \overline{\text{sat}}_{\delta}$ denote two saturation functions. Consider control gains $k_1, k_2 > 0$ satisfying (12) with C_{δ} defined by (2), and the additional condition

$$k_1 \delta_M + k_2 \overline{\delta}_M + |\dot{p}_r|_s < g \quad (17)$$

Define a dynamic augmentation

$$\dot{\eta} = \eta \times \omega - k_3(\eta - \tilde{\sigma}), \quad k_3 > 0 \quad (18)$$

together with the control law

$$\begin{cases} \omega_1 &= -\frac{k_4|\mu|\mu_2}{(|\mu|+\mu_3)^2} - \frac{1}{|\mu|^2}\mu^T S(e_1)\varpi \\ \omega_2 &= \frac{k_4|\mu|\mu_1}{(|\mu|+\mu_3)^2} - \frac{1}{|\mu|^2}\mu^T S(e_2)\varpi \\ u &= \mu_3 \end{cases} \quad (19)$$

with $k_4 > 0$ and μ and ϖ defined by:

$$\begin{aligned} \mu &:= \gamma + k_1 \text{sat}_\delta(\eta) + k_2 \overline{\text{sat}}_\delta(\tilde{v}) - a_r \\ \varpi &:= -k_1 k_3 \left[s_\delta(|\eta|^2) I_3 + 2s'_\delta(|\eta|^2) \eta \eta^T \right] (\eta - \tilde{\sigma}) \\ &\quad + k_2 \left[\overline{s}_\delta(|\tilde{v}|^2) I_3 + 2\overline{s}'_\delta(|\tilde{v}|^2) \tilde{v} \tilde{v}^T \right] (\gamma - u e_3) \end{aligned} \quad (20)$$

with \tilde{v} and a_r defined by (10) and (11). Then,

i) if **A1**, **A2**, and **A3** hold then, there exists $\underline{k}_3 > 0$ such that, for any $k_3 > \underline{k}_3$, $(p, \dot{p}, q, \eta) = (p_r, \dot{p}_r, q_r, 0)$ is a (uniformly) AS and LES equilibrium trajectory for the closed-loop system (5)-(18)-(19)-(20) with CD

$$\mathcal{A} := \{(p, \dot{p}, q, \eta)(0) : \mu(0) \neq -|\mu(0)|e_3\} \quad (21)$$

ii) if **A1** and **A3** hold then, for any $\rho > 0$, there exist $\vartheta, \underline{k}_3 > 0$ such that, for any $k_3 > \underline{k}_3$ and any M with $|\dot{M}|_s < \vartheta$, $(p, \dot{p}, q, \eta) = (p_r, \dot{p}_r, q_r, 0)$ is an AS and LES equilibrium trajectory for the closed-loop system (5)-(18)-(19)-(20) with CD containing

$$\mathcal{A}_\rho := \{(p, \dot{p}, q, \eta)(0) : |(\tilde{p}(0), \tilde{v}(0), \eta(0))| \leq \rho, \mu(0) \neq -|\mu(0)|e_3\} \quad (22)$$

Let us discuss the links between this result and Proposition 1. First, except for the γ term, μ in (20) is reminiscent of the control law (13) with $\tilde{\sigma}$ replaced by η . In view of (18), this latter variable can be viewed as a "filtered value" of $\tilde{\sigma}$. The important point is that $\dot{\eta}$ is known, since it is explicitly given by (18), while the time derivative of $\tilde{\sigma}$ is not, since M is unknown. Then, the control inputs u, ω_1, ω_2 are defined so that μ converges to $|\mu|e_3$. This implies, using the second equality in (15), that \dot{p} converges to $R(-k_1 \text{sat}_\delta(\eta) - k_2 \overline{\text{sat}}_\delta(\tilde{v}) + a_r)$. This expression is the same as (8)-(13) with $\tilde{\sigma}$ being replaced by η . This explains the relation between Propositions 1 and 2. Finally,

$$\begin{aligned} &|k_1 \text{sat}_\delta(\eta) + k_2 \overline{\text{sat}}_\delta(\tilde{v}) - a_r| \\ &\leq k_1 \delta_M + k_2 \bar{\delta}_M + |\dot{p}_r|_s \leq g = |\gamma| \end{aligned} \quad (23)$$

where the second inequality comes from (17). This inequality implies that:

Lemma 1 $\mu(0) \neq -|\mu(0)|e_3$ if

$$\gamma_3(0) > -\sqrt{g^2 - (k_1 \delta_M + k_2 \bar{\delta}_M + |\dot{p}_r|_s)^2} \quad (24)$$

Since $\gamma_3 = gq_3$, Lemma 1 implies that in both cases *i)* and *ii)* the CD in roll/pitch contains the upper hemisphere. Note that Condition (24) is *conservative*. Thus, in both cases *i)* and *ii)*, a large stability domain in orientation is guaranteed. Global stability is ruled out because q belongs to a compact set (i.e., the unit sphere). If (24) is satisfied, there is no constraint on the initial values of position, linear velocity, and dynamic augmentation variables in case *i)* (see (21)). In case *ii)*, initial values can be made arbitrarily large under conditions on k_3 and \dot{M} .

4.1. Simplified control law

Another control expression with similar robustness properties is proposed next. It involves a simpler control expression and does not require the dynamic extension (18).

Proposition 3 With the notation of Prop. 2, assume that the following extra condition on the gains k_1, k_2 is satisfied:

$$k_1 \delta_M + k_2 \bar{\delta}_M + |\dot{p}_r|_s \leq g(1 - \varkappa), \quad 0 < \varkappa < 1 \quad (25)$$

and define the control law as:

$$\begin{cases} \omega_1 &= -k_4 \mu_2, \quad \omega_2 &= k_4 \mu_1 \\ u &= \mu_3 \end{cases} \quad (26)$$

with

$$\mu := \gamma + k_1 \text{sat}_\delta(\tilde{\sigma}) + k_2 \overline{\text{sat}}_\delta(\tilde{v}) - a_r \quad (27)$$

Then,

i) If **A1**, **A2**, and **A3** hold then, for any $\rho > 0$, there exists $k_{4,\rho} > 0$ such that, for any $k_4 > k_{4,\rho}$, $(p, \dot{p}, q) = (p_r, \dot{p}_r, q_r)$ is a (uniformly) AS and LES equilibrium trajectory for the closed-loop system (5)-(26)-(27), with CD containing

$$\begin{aligned} \mathcal{A}_\rho &:= \{(p, \dot{p}, q)(0) : |\tilde{v}(0)| < \rho, \\ &|\mu_1(0), \mu_2(0)| < g\varkappa / \sqrt{2}, \mu_3(0) > 0\} \end{aligned} \quad (28)$$

ii) If **A1** and **A3** hold then, for any $\rho > 0$, there exist $\vartheta, \underline{k}_4 > 0$ such that, for any $k_4 > \underline{k}_4$ and any M with $|\dot{M}|_s < \vartheta$, $(p, \dot{p}, q) = (p_r, \dot{p}_r, q_r)$ is an AS and LES equilibrium trajectory for the closed-loop system (5)-(26)-(27) with CD containing

$$\begin{aligned} \mathcal{A}_\rho &:= \{(p, \dot{p}, q)(0) : |\tilde{p}(0)| < \rho, |\tilde{v}(0)| < \bar{\delta}_m/2, \\ &|\mu_1(0), \mu_2(0)| < g\varkappa / \sqrt{2}, \mu_3(0) > 0\} \end{aligned} \quad (29)$$

The main assets of Proposition 3 are a large stability domain, robustness to position measurement uncertainties, and the simplicity of the control expression. Concerning the latter aspect, the fact that the control expression is essentially linear (modulo saturation functions) is clearly an asset with respect to the control law of Proposition 2, e.g., when considering effects of measurement noise. Another asset is related to the extension of the present analysis to the full model (4) (i.e., considering Γ as control input instead of ω). A classical solution in this case would be a linear torque feedback with feedforward action. Computing the feedforward action requires to differentiate angular velocity inputs proposed above. Differentiating ω_1, ω_2 in (26) is much simpler than for (19) and requires much less information. In addition, one may want in this case to replace $\tilde{\sigma}$ in (27) by η given by (18) since $\dot{\eta}$ is known. Additional work is needed for the stability analysis of such a torque control law and this issue is left for future research.

Another common approach to extend the controller from kinematics to dynamics is to use a high gain controller: $\Gamma = -J\omega \times \omega - kJ(\omega - \omega^d)$ with k chosen large enough and ω^d the kinematic controller Hua et al. (2009); Brescianini and D'Andrea (2016). This simple solution is motivated by a time separation argument. To the authors' knowledge its stability analysis remains an open issue.

5. Extensions to GPS-denied environments

This section considers extension of the results of Section 4 to velocity-free scenarios, i.e., when velocity v is not measured. This is a challenging problem and we only consider a special case of the general framework addressed in Section 4. We will show in the application section, however, that this special case covers important scenarios.

Let $v_M := R^T M \dot{p}$. Assume that M and p_r are constant values. Then, $v_M = R^T M \dot{\tilde{p}}$ and it follows from (6) that

$$\begin{cases} \dot{\tilde{\sigma}} &= \tilde{\sigma} \times \omega + v_M \\ \dot{\hat{v}}_M &= v_M \times \omega + R^T M \ddot{p} \end{cases} \quad (30)$$

We want to obtain an estimation of the non-measured variable v_M . To this purpose, consider the following observer:

$$\begin{cases} \dot{\hat{\sigma}} &= \hat{\sigma} \times \omega + \hat{v}_M - 2\alpha k(\hat{\sigma} - \tilde{\sigma}) \\ \dot{\hat{v}}_M &= \hat{v}_M \times \omega - k^2(\hat{\sigma} - \tilde{\sigma}) \end{cases} \quad (31)$$

Proposition 4 Let $e_\sigma := \hat{\sigma} - \tilde{\sigma}$ and $e_v := \hat{v}_M - v_M$ denote the estimation errors. Assume that there exists a constant C such that, for any initial condition, $|\dot{p}(t)| \leq C$, $\forall t$. Then, for any $\varepsilon > 0$ and any $\alpha > 0$ there exists $k_m > 0$ such that, for any $k \geq k_m$ and any initial condition $(\hat{\sigma}(0), \hat{v}_M(0))$, $|e_\sigma| + |e_v|$ is ultimately bounded by ε .

From Proposition 4 a good estimate of v_M can be built from the measurement $\tilde{\sigma}$ if \ddot{p} is bounded. Note that the control laws derived in Section 4 ensure the boundedness of \ddot{p} . This suggests to use such control laws with \hat{v}_M as velocity input in place of v . In the rest of this section, we focus on the stability analysis of these control laws with v_M as velocity input. By doing so, we neglect the discrepancy between \hat{v}_M and v_M knowing that, from Proposition 4, it can be made arbitrarily small ultimately. Stability analysis of the couple controller/observer is left for future studies.

The rest of this section will invoke Assumptions 1, 2, and 4. Note that, when p_r is a constant vector, the control law u in (13) can be written as $u := k_1 \text{sat}_\delta(\tilde{\sigma}) + k_2 \overline{\text{sat}}_\delta(v)$. The following propositions show that the results of Section 4 can be extended to the case of velocity measurements v_M with minor modifications. Due to space limitations, we only address extension of Propositions 1 and 3.

Proposition 5 Let $\text{sat}_\delta, \overline{\text{sat}}_\delta$ denote two \mathbb{R}^3 -valued saturation functions with associated functions s_δ, \bar{s}_δ . Consider control gains $k_1, k_2 > 0$ such that

$$\begin{cases} k_2^2 |M|_i^2 > k_1 |M_a M^{-1}|_s \max \{ C_\delta |M|_s, |M_a M^{-1}|_s |M|_i \} \\ k_2 \bar{\delta}_m |M|_i > k_1 \delta_m |M|_s \end{cases} \quad (32)$$

and define the control law

$$u := k_1 \text{sat}_\delta(\tilde{\sigma}) + k_2 \overline{\text{sat}}_\delta(v_M) \quad (33)$$

If **A1**, **A2**, and **A4** hold then $(p, \dot{p}) = (p_r, 0)$ is a (uniformly) GAS and LES equilibrium point for the closed-loop system (8)-(33).

Proposition 6 Let $\text{sat}_\delta, \overline{\text{sat}}_\delta$ denote two saturation functions. Consider control gains $k_1, k_2 > 0$ satisfying (32) with C_δ be defined by (2), and the additional condition

$$k_1 \delta_m + k_2 \bar{\delta}_m \leq g(1 - \varkappa), \quad 0 < \varkappa < 1 \quad (34)$$

and consider the control law (26) with

$$\mu := \gamma + k_1 \text{sat}_\delta(\tilde{\sigma}) + k_2 \overline{\text{sat}}_\delta(v_M) \quad (35)$$

If **A1**, **A2**, and **A4** hold then, for any $\rho > 0$, there exists $k_{4,\rho} > 0$ such that, for any $k_4 > k_{4,\rho}$, $(p, \dot{p}, q) = (p_r, 0, q_r)$ is a (uniformly) AS and LES equilibrium point for the closed-loop system (5)-(26)-(35), with CD containing

$$\mathcal{A}_\rho := \{(p, \dot{p}, q)(0) : |v_M(0)| < \rho, |(\mu_1(0), \mu_2(0))| < g\varkappa/\sqrt{2}, \mu_3(0) > 0\} \quad (36)$$

6. Application to visual servoing of UAVs

Micro UAVs (MAVs) are increasingly used for surveillance and inspection applications. Controlling such systems through vision sensors is an important issue. A first solution consists in using a stereo vision system. When MAVs operate far from ground/obstacles, however, the advantage of a stereo system w.r.t. a *mono-camera* system is questionable since the quality of depth-estimation is then poor due to the short baseline. In fact, a mono-camera system can be preferred for simplicity and because image processing can be performed at a higher frame-rate. Thus, much attention has been paid to mono-camera visual servoing of UAVs (see, e.g., Saripalli et al. (2003); Conte and Doherty (2008); Caballero et al. (2009); Cunha et al. (2011); Mondragon et al. (2010)). These approaches often rely on the estimation of the so-called "Homography matrix", which embeds information on the camera's pose. However, the relation between the Homography matrix and the pose involves quantities that may be poorly known. This issue is often resolved in the literature by considering restrictive scenarios (e.g., perfectly calibrated camera, camera observing an horizontal ground, knowledge of the vehicle's altitude, etc). We show next that our results provide stability guarantees for a much larger range of scenarios.

6.1. Preliminary recalls and problem statement

Consider an underactuated UAV with a video camera facing a planar target. Suppose that a "reference" picture of this target taken at a reference pose is known. This reference pose is represented on Fig. 1 by the reference frame \mathcal{R}^* . We assume that this pose is a possible equilibrium for the dynamics of this underactuated vehicle, meaning that the z axis of \mathcal{R}^* is vertical. Otherwise, asymptotic stabilization of this pose is not possible. We also assume that the optical center of the camera corresponds to the vehicle's center of mass and the optical axis corresponds to the x -axis of \mathcal{R}^* . At every time, the "current" picture of the target, taken at the current pose represented by the frame \mathcal{R} , is compared to the reference one. From there, the *homography matrix* is computed (see e.g. Ma et al. (2003)).

This matrix, which transforms the target's points coordinates from the reference pose to the current pose, is

$$H := R^T - \frac{1}{d^*} R^T p n^{*T} \quad (37)$$

with d^* the distance from the UAV reference position to the target plane and n^* the normal to this plane expressed in the reference frame. Both d^* and n^* are unknown and thus unavailable for the control design. We show next that for any orientation of the visual target one can extract from H position measurements of the form (6). The case of a non-vertical target is first briefly described. Then, the case of a vertical target is studied in more details.

6.2. Non-vertical target

In this case, $n_3^* := n^{*T} e_3 > 0$ and it follows from (37) that $He_3 = R^T e_3 - (n_3^*/d^*) R^T p = \frac{\gamma}{g} - \frac{n_3^*}{d^*} R^T p$. As recalled in Section 4, γ is usually estimated from the UAV's IMU. By subtracting $\frac{\gamma}{g}$ to He_3 , one obtains the measurement $\tilde{\sigma} = \frac{n_3^*}{d^*} R^T p = R^T M p$ with $M = \frac{n_3^*}{d^*} I > 0$. Since M is constant and diagonal, it satisfies all the conditions in Assumptions 1, 2, and 4. All the results of Sections 4 and 5 apply and yield stability conditions in term of the control gains and the constant number n_3^*/d^* .

Figure 1: Problem scheme

6.3. Vertical target, i.e. $n_3^* = 0$

This case is of interest in many inspection applications since many man-made buildings are vertical. Let

$$\tilde{\sigma} := (He_2) \times (He_3) - He_1, \quad \gamma := gHe_3 \quad (38)$$

From (37) and the assumption $n_3^* = 0$, one can verify that

$$\tilde{\sigma} = R^T M \left(\frac{n_1^*}{d^*} \right) p, \quad \gamma = gR^T e_3 \quad (39)$$

with $M(\tau) := \tau_1 I + S(\tau_2 e_3)$. Thus, $\tilde{\sigma}$ and γ satisfy Eq. (6), (14) with $p_r = 0$. Note that $M_s(\tau) = \tau_1 I$ and $M_a(\tau) = S(\tau_2 e_3)$ commute for any τ . Thus, like for a non-vertical target, M satisfies all the conditions in Assumptions 1, 2, and 4. We detail below application of our results to fixed-point stabilization and way-points navigation.

Vision based point stabilization. Let us first address the stabilization of the UAV at the reference pose. From (39), Proposition 2-i) applies directly with $M = M\left(\frac{n_1^*}{d^*}\right)$ provided the gain conditions (12) and (17) are satisfied. We deduce that the control law (18)-(19) ensures asymptotic stabilization of the reference pose (with global convergence domain in position/velocity) if:

$$\begin{aligned} & a) n_1^*, k_1, k_2 > 0 \quad b) k_2 \bar{\delta}_m > k_1 \delta_M \\ & c) k_1 \delta_M + k_2 \bar{\delta}_M < g \quad d) n_1^* d^* k_2^2 > k_1 |n_2^*| \left(|n_2^*| + \frac{2n_1^*}{3\sqrt{3}} \right) \end{aligned}$$

Condition $n_1^* > 0$, which ensures that $M > 0$, means that the camera is "facing" the target at the reference pose (obvious condition in practice). Given bounds on the uncertain parameters d^*, n^* , i.e., $d^* \in [\underline{d}^*, \bar{d}^*]$, $n_1^* \in [\underline{n}_1^*, 1]$, Condition d) can be replaced by: $\underline{n}_1^* \underline{d}^* k_2^2 > k_1 (1 + 2/(3\sqrt{3}))$. Thus, one obtains stability conditions on the control parameters given bounds on the uncertain parameters d^*, n^* .

Yaw control. The yaw degree of freedom is not involved in the stabilization objective. In practice, it matters to keep the target inside the field of view of the camera. We propose the following yaw control law: $\omega_3 = k_5 H_{21}$. Upon convergence of the position, velocity, roll and pitch errors to zero, the yaw dynamics will be close to $\dot{\psi} \approx -k_5 \sin \psi$, thus ensuring the convergence of ψ to zero unless $\psi(0) = \pi$ (a case contradictory with the visibility assumption).

Visual-based way-points navigation. Consider a sequence of reference images of a planar scene taken from different reference frames (hereafter referred to as way-points). The objective is to make the UAV navigate along this sequence of way-points. Without loss of generality, we consider two way-points. From the two reference images and the current image, one can define two homography matrices, from which are computed two uncertain relative position measurements $\tilde{\sigma}_1, \tilde{\sigma}_2$ as defined by Eq. (38). Let p_i denote the position vector of the current frame w.r.t. the i -th reference frame and R_i denote the rotation matrix from the current frame to the i -th reference frame. If χ (resp. χ_i^*) denotes the coordinate vector of a point of the scene in the current frame (resp. in the i -th reference frame), then $\chi_1^* = R_1 \chi + p_1$ and $\chi_2^* = R_2 \chi + p_2$. The transformation between the two reference frames is defined as $\chi_2^* = \bar{R} \chi_1^* + \bar{p}$ where \bar{R} is a constant matrix and \bar{p} is a constant vector, and one has $R_2 = \bar{R} R_1$ and $p_2 = \bar{R} p_1 + \bar{p}$. We implicitly define a reference trajectory by considering a time-varying interpolation $\tilde{\sigma}$ of $\tilde{\sigma}_1$ and $\tilde{\sigma}_2$: $\tilde{\sigma} := (1 - \lambda(t)) \tilde{\sigma}_1 + \lambda(t) \tilde{\sigma}_2$ with λ an increasing function ranging over $[0, 1]$. Consider the generic case where both parameters n^*, d^* change between the two reference images. Then, we deduce from the above relations that

$$\begin{cases} \tilde{\sigma} &= R_1^T \bar{M} (p_1 - p_r) \\ \bar{M}(t) &:= (1 - \lambda(t)) M\left(\frac{n_1}{d_1}\right) + \lambda(t) \bar{R}^T M\left(\frac{n_2}{d_2}\right) \bar{R} \\ p_r(t) &:= -\lambda(t) \bar{M}(t)^{-1} \bar{R}^T M\left(\frac{n_2}{d_2}\right) \bar{p} \end{cases} \quad (40)$$

Thus, $\tilde{\sigma}$ is of the form of Eq. (6) with $M(t)$ replaced by $\bar{M}(t)$. Proposition 2-ii) can then be used to ensure semi-global stability of this non-stationary reference trajectory. Note that the

existence of $|\bar{M}|_i > 0$, $|\bar{M}|_s < +\infty$ and $|\dot{\bar{M}}|_s < +\infty$ in Assumption **A1** for the matrix $\bar{M}(\cdot)$ follows from the fact that $M > 0$ and $\lambda(t) \in [0, 1]$. Thus, the linear interpolation of $\bar{\sigma}_1$ and $\bar{\sigma}_2$ implicitly defines a reference trajectory with compact image set. Compactness plays a key role in ensuring that Assumption **A1** is satisfied.

7. Simulation results

We illustrate the results of this paper for the visual servoing applications of Section 6, in the case of a vertical visual target. We first consider the fixed-point stabilization problem. The initial conditions and scene parameters at the reference pose are:

$$\begin{cases} p_0 = (-5.5\text{m}; 1.2\text{m}; 1.3\text{m})^T \\ v_0 = (-2.3\text{m}\cdot\text{s}^{-1}; -1.6\text{m}\cdot\text{s}^{-1}; 0.4\text{m}\cdot\text{s}^{-1})^T \\ \phi_0 = -0.5^\circ, \theta_0 = 11.4^\circ, \psi_0 = 4.1^\circ \\ n^* = (0.7; -0.71; 0)^T, d^* = 3\text{m} \end{cases} \quad (41)$$

For the simulation reported on Fig. 2, the control law of Prop. 2 is used with $\eta(0) = 0$. For the simulation reported on Fig. 3, the simplified controller of Prop. 3 is used. For the simulation reported on Fig. 4, the velocity-free controller of Prop. 6 is used with v_M replaced by \hat{v}_M and \hat{v}_M the output of the observer (31). The control gains are $[k_1, k_2, k_3, k_4, k_5] = [1, 1.5, 1, 1, 1]$ and the saturation functions $\text{sat}_\delta, \text{sat}_{\bar{\delta}}$ are defined from the expression (3) of the associated functions s_δ, \bar{s}_δ , with $\delta = [.9; 1]$, $\bar{\delta} = [1; 1.1]$. The gains of the observer (31) are $k = 7, \alpha = 0.7$ and $\hat{\sigma}(0) = \hat{v}_M(0) = 0$. All controllers stabilize the system. Transient behaviors are qualitatively similar but differences can be noticed. With respect to the control law of Prop. 2, the simplified control law of Prop. 3 yields a shorter settling time, less overshoot, and smaller angular velocities. The velocity-free control law of Prop. 6 yields results similar to that of the first simulation but the convergence of the angular velocity to zero is slower. From Fig. 4 one can also conjecture asymptotic stability of the couple observer/controller, i.e., asymptotic convergence of \hat{v}_M to v_M and of the tracking error to zero.

Figure 2: Fixed-point stabilization: control law of Proposition 2.

Validation of the visual way-points navigation, with the control law of Prop. 3 and $\bar{\sigma}$ defined by (40), is presented on

Figure 3: Fixed-point stabilization: control law of Proposition 3.

Figure 4: Fixed-point stabilization: control law of Proposition 6.

Fig. 5. The interpolation function λ is defined as: $\lambda(t) = 0$ for $t \leq t_s$, $\lambda(t) = 1$ for $t \geq t_e$ and $\lambda(t) = \frac{t-t_s}{t_e-t_s}$ for $t_s < t < t_e$ with $t_s = 50\text{s}, t_e = 80\text{s}$. Initial conditions and scene parameters for the first image are still given by (41). Scene parameters for the second image (i.e., second way-point) are $n^* = (0.87, -0.5, 0)^T, d^* = 1/3\text{m}$. The position vector between the two way-points is defined by $\bar{p} = (-5, 10, 20)^T$. Let us notice the smooth transition and small control input values on the transition interval.

Figure 5: Way-points navigation: control law of Proposition 3.

8. Conclusion

We have proposed a feedback control design and robustness analysis for the stabilization of a class of underactuated vehicles with uncertain position measurements. Strong stability results have been obtained for a large class of position measurements uncertainties and sufficient stability conditions on the control gains have been derived in relation with the norm of the uncertainties. We have shown direct applications of these results to UAVs for two visual servoing problems: fixed-point stabilization and visual way-points navigation w.r.t. a planar scene. Simulation results support the proposed analysis.

Proof of Propositions

Proof of Proposition 1: From (6), $x := R\tilde{\sigma} = M\tilde{p}$. From (9)-(11) $y := R\tilde{v} = \dot{\tilde{p}}$. Thus, $\dot{x} = My + M\dot{\tilde{p}}$ and, from (8), (11) and (13), $\dot{y} = -R(k_1 \text{sat}_\delta(\tilde{\sigma}) + k_2 \overline{\text{sat}}_\delta(\tilde{v}))$. From Definition 1-i), $R \text{sat}_\delta(\xi) = \text{sat}_\delta(R\xi)$ for any ξ . Therefore, the closed-loop system in (x, y) coordinates is given by:

$$\begin{cases} \dot{x} = My + M\dot{\tilde{p}} \\ \dot{y} = -k_1 \text{sat}_\delta(x) - k_2 \overline{\text{sat}}_\delta(y) \end{cases} \quad (42)$$

Lemma 2 Let y denote a solution of the equation

$$\dot{y} = -k_1 \text{sat}_\delta(x) - k_2 \overline{\text{sat}}_\delta(y) + \varrho(t) \quad (43)$$

with x any time-function and ϱ a bounded and continuous time-function such that, for some $t_1 \geq 0$ and $c_\varrho > 0$,

$$|\varrho(t)| \leq k_2 \bar{\delta}_m - k_1 \delta_M - c_\varrho, \quad \forall t \geq t_1 \quad (44)$$

Then, there exists a continuous function T such that, for $t \geq T(y(0))$, $\overline{\text{sat}}_\delta(y(t)) = y(t)$, i.e., the function $\overline{\text{sat}}_\delta$ desaturates after time $T(y(0))$.

Property i): Assumption A2 implies that $\dot{M} = 0$. Applying Lemma 2 to the second equation in (42) with $\varrho \equiv 0$ and using the second condition in (12), one deduces that along any solution of System (42) the function $\overline{\text{sat}}_\delta$ desaturates after some time and the solution then satisfies:

$$\begin{cases} \dot{x} = My \\ \dot{y} = -k_1 \text{sat}_\delta(x) - k_2 y = -k_1 s_\delta(|x|^2)x - k_2 y \end{cases} \quad (45)$$

Consider the CLF (Candidate Lyapunov Function) V defined by:

$$\begin{aligned} V(x, y) &= k_1 \int_0^{|x|^2} s_\delta(\tau) d\tau + y^T M y \\ &\quad + \frac{2k_1}{k_2} s_\delta(|x|^2) x^T M a_y + \kappa s_\delta(|x|^2) x^T y \\ &= k_1 \int_0^{|x|^2} s_\delta(\tau) d\tau + y^T M y \\ &\quad + \frac{2k_1}{k_2} \text{sat}_\delta(x)^T M a_y + \kappa \text{sat}_\delta(x)^T y \end{aligned} \quad (46)$$

where κ is a constant positive number. We show that V is a Lyapunov function for κ small enough. Let

$$\begin{cases} \bar{\kappa} := k_2^2 |M|_i - k_1 |M|_s |M|_s C_\delta > 0 \\ \kappa_1 := 2 \sqrt{k_1 |M|_i} - 2 \frac{k_1}{k_2} |M|_s > 0 \\ \kappa_2 := \frac{2\bar{\kappa}}{k_2 |M|_s C_\delta} > 0 \\ \kappa_3 := \frac{2\bar{\kappa}}{k_2 |M|_s C_\delta + \frac{k_2^3}{4k_1}} > 0 \\ 0 < \kappa < \min \{ \kappa_1, \kappa_2, \kappa_3 \} \end{cases} \quad (47)$$

where positivity of $\bar{\kappa}, \kappa_1$ follows from (12) and positivity of κ_2, κ_3 is a consequence thereof. We first prove that V is positive definite and proper. Integrating by part and using the fact that $s'_\delta(\tau) \leq 0 \forall \tau$ due to Def. 1-iii), we get

$$\int_0^{|x|^2} s_\delta(\tau) d\tau = - \int_0^{|x|^2} \tau s'_\delta(\tau) d\tau + |x|^2 s_\delta(|x|^2) \geq |x|^2 s_\delta(|x|^2)$$

From (1), $s_\delta(|x|^2) \leq \sqrt{s_\delta(|x|^2)}$. Therefore, from (46),

$$V \geq k_1 |x|^2 s_\delta(|x|^2) - \left(\frac{2k_1}{k_2} |M|_s + \kappa \right) \sqrt{s_\delta(|x|^2)} |x| |y| + |M|_i |y|^2$$

Therefore, V is positive definite provided that

$$b^2 < 4k_1 |M|_i, \quad b := \frac{2k_1}{k_2} |M|_s + \kappa \quad (48)$$

which is equivalent to $\kappa < \kappa_1$. Since $s_\delta(\tau) > 0$ for $\tau \neq 0$ this ensures that V is a positive definite function of x and y , and V is proper due to (1). Let us now prove that V is non-increasing along the solutions of System (45). Differentiating V along these solutions yields

$$\begin{cases} \dot{V} = -2k_2 y^T M_s y - 2 \frac{k_1}{k_2} y^T M_a F_\delta(x) M y \\ \quad - \kappa k_1 s'_\delta(|x|^2) |x|^2 + \kappa y^T F_\delta(x) M y \\ \quad - \kappa k_2 s'_\delta(|x|^2) x^T y \\ F_\delta(x) := s_\delta(|x|^2) I_3 + 2s'_\delta(|x|^2) x x^T \end{cases} \quad (49)$$

By (2), $|F_\delta(x)| \leq C_\delta, \forall x$ and we deduce that

$$\begin{aligned} \dot{V} &\leq -C_{1,1} |y|^2 + C_{1,2} |y| s_\delta(|x|^2) |x| - C_{1,3} s_\delta^2(|x|^2) |x|^2 \\ &\leq -C_{1,1} |y|^2 + C_{1,2} |y| |\text{sat}_\delta(x)| - C_{1,3} |\text{sat}_\delta(x)|^2 \end{aligned} \quad (50)$$

with

$$C_{1,1} := 2k_2 |M|_i - b |M|_s C_\delta, \quad C_{1,2} := \kappa k_2, \quad C_{1,3} := \kappa k_1 \quad (51)$$

The right-hand side of (50) is a quadratic form in $|y|$ and $|\text{sat}_\delta(x)|$. Therefore, \dot{V} is negative definite provided that

$$a) C_{1,1} > 0, \quad b) C_{1,3} > 0, \quad c) C_{1,2}^2 < 4C_{1,1} C_{1,3} \quad (52)$$

Condition a) follows from the fact that $\kappa < \kappa_2$. Condition b) holds true for any $\kappa > 0$ since $k_1 > 0$, and Condition c) follows from the fact that $\kappa < \kappa_3$. Thus, $\exists \beta > 0$ such that

$$\dot{V} \leq -\beta (|y|^2 + |\text{sat}_\delta(x)|^2) \quad (53)$$

This shows global asymptotic stability of $(p, \dot{p}) = (p_r, \dot{p}_r)$. Local exponential stability readily follows by noting that both V and \dot{V} are locally quadratic in x and y around the origin, i.e., from Def. 1-ii), $s_\delta(\tau) = 1$ for $\tau \leq \delta_m$.

Property ii): Since $|y| = |\tilde{v}|$, $(p(0), \dot{p}(0)) \in \mathcal{A}_\rho$ implies that $|y(0)| \leq \rho$. Applying Lemma 2 to System (42) with $\varrho \equiv 0$ and using the continuity property of the function T in Lemma 2, one deduces that for any $t \geq T_\rho := \max_{|y| \leq \rho} T(y)$ and along any solution with initial condition in \mathcal{A}_ρ , $\overline{\text{sat}}_\delta$ desaturates and the solution satisfies

$$\begin{cases} \dot{x} = My + M\dot{\tilde{p}} \\ \dot{y} = -k_1 \text{sat}_\delta(x) - k_2 y \end{cases} \quad (54)$$

From (6) and (7),

$$\forall t, \quad |M|_i |\tilde{p}(t)| \leq |x(t)| = |M(t)\tilde{p}(t)| \leq |M|_s |\tilde{p}(t)| \quad (55)$$

Therefore, $|(x(0), y(0))| \leq \rho \max(1, |M|_s)$ for $(p(0), v(0)) \in \mathcal{A}_\rho$. Assumption **A1**, (54), and (55) imply that $|(\dot{x}, \dot{y})| \leq k|(x, y)|$ for some constant k . As a consequence, there exists a constant $\bar{\rho}$ such that, along any solution with initial condition in \mathcal{A}_ρ , $|(x(T_\rho), y(T_\rho))| \leq \bar{\rho}$.

Consider V defined by (46) as a CLF for System (54). Its derivative along the solutions of this system satisfies

$$\begin{aligned} \dot{V} &= \dot{V}|_{Case\ i} + 2k_1 s_\delta (|x|^2) x^T \dot{M} \tilde{p} \\ &\quad + 2 \frac{k_1}{k_2} \tilde{p}^T \dot{M}^T F_\delta(x) M_{a,y} + \kappa \tilde{p}^T \dot{M}^T F_\delta(x) y \\ &\quad + y^T \dot{M} y + 2 \frac{k_1}{k_2} s_\delta (|x|^2) x^T \dot{M}_{a,y} \end{aligned} \quad (56)$$

with F_δ given by (49) and $\dot{V}|_{Case\ i}$ the expression (49) of \dot{V} . Using (55) then implies that for any M with $|M|_s < \vartheta$,

$$\begin{aligned} \dot{V} &\leq \dot{V}|_{Case\ i} + \vartheta \left[\frac{2k_1}{|M|_i} s_\delta (|x|^2) |x|^2 + |y|^2 \right. \\ &\quad \left. + \left(2 \frac{k_1}{k_2} |M_{a,s}| + \kappa \right) \frac{C_\delta}{|M|_i} + 2 \frac{k_1}{k_2} s_\delta (|x|^2) \right] |x||y| \\ &\leq - (C_{1,1} - \vartheta) |y|^2 - C_{1,3} |\text{sat}_\delta(x)|^2 \\ &\quad + (C_{1,2} + 2 \frac{k_1}{k_2} \vartheta) |\text{sat}_\delta(x)||y| \\ &\quad + \frac{2k_1}{|M|_i} \vartheta |x| |\text{sat}_\delta(x)| + \left(2 \frac{k_1}{k_2} |M_{a,s}| + \kappa \right) \frac{C_\delta}{|M|_i} \vartheta |x||y| \end{aligned} \quad (57)$$

Let:

$$\begin{aligned} V_M &:= \max_{|(x,y)| \leq \bar{\rho}} V(x, y) > 0 \\ x_M &:= \max_{(x,y)/V(x,y) \leq V_M} |x| > 0 \\ s_m &:= \min_{|x| \leq x_M} s_\delta (|x|^2) > 0 \end{aligned} \quad (58)$$

V_M exists because V is continuous and $V_M > 0$ because V is positive definite. x_M exists because V is radially unbounded and $x_M > 0$ because $V_M > 0$. Finally, s_m exists because s_δ is continuous and $s_m > 0$ because otherwise s_δ vanishes at some point, which contradicts *ii*) of Definition 1. From the definition of s_m , note that

$$|x| \leq x_M \implies |x| = \left| \frac{s_\delta (|x|^2) x}{s_\delta (|x|^2)} \right| \leq \frac{1}{s_m} |\text{sat}_\delta(x)| \quad (59)$$

Therefore, as long as $|x| \leq x_M$, it follows from (57) that

$$\dot{V} \leq -C_{2,1} |y|^2 + C_{2,2} |y| |\text{sat}_\delta(x)| - C_{2,3} |\text{sat}_\delta(x)|^2 \quad (60)$$

with

$$\begin{cases} C_{2,1} &:= C_{1,1} - \vartheta \\ C_{2,2} &:= C_{1,2} + \left[2 \frac{k_1}{k_2} + \left(2 \frac{k_1}{k_2} |M_{a,s}| + \kappa \right) \frac{C_\delta}{s_m |M|_i} \right] \vartheta \\ C_{2,3} &:= C_{1,3} - \frac{2k_1}{s_m |M|_i} \vartheta \end{cases} \quad (61)$$

From the above expression, the $C_{2,j}$'s tend to the $C_{1,j}$'s as ϑ tends to zero. Thus, it follows from (52) that for $\vartheta > 0$ small enough and κ satisfying (47), the right-hand side of (60) is a negative-definite quadratic form in $|y|$ and $|\text{sat}_\delta(x)|$. We thus have shown that for $\vartheta > 0$ small enough, $0 \neq |x| \leq x_M \implies \dot{V} < 0$. From the definition of x_M , we deduce that $0 \neq V \leq V_M \implies \dot{V} < 0$. From the definition of V_M and the fact that $|(x(T_\rho), y(T_\rho))| \leq \bar{\rho}$ along any solution with initial condition in

\mathcal{A}_ρ , this implies convergence of (x, y) to zero along these solutions. Local exponential stability is proved as for Property *i*). ■

Proof of Proposition 2: It builds on the proof of Prop. 1. Recall from Prop. 1 that $x = M\tilde{p}$ and $y = \tilde{p}$. In addition, let $z := R\eta$ and $\tilde{\mu} := \mu - \mu_3 e_3$. Using the expression (15) of \tilde{p} , the expression of u in (19), and (18), one obtains (compare with (42)):

$$\begin{cases} \dot{x} &= My + \dot{M}\tilde{p} \\ \dot{y} &= -k_1 \text{sat}_\delta(z) - k_2 \overline{\text{sat}_\delta}(y) + R\tilde{\mu} \\ \dot{z} &= -k_3(z - x) \end{cases} \quad (62)$$

Lemma 3 With ω_1, ω_2 defined by (19), $\tilde{\mu} = 0$ is LES. More precisely, $\exists \bar{c}, \alpha > 0 : |\tilde{\mu}(t)| \leq \bar{c} |\tilde{\mu}(0)| e^{-\alpha t}$, $\forall t$, for any initial condition such that $\mu(0) \neq -|\mu(0)| e_3$.

Property i): Assumption **A2** implies that $\dot{M} = 0$. From Lemma 3 $\tilde{\mu}$ tends to zero and from (12) $k_1 \delta_M - k_2 \bar{\delta}_m < 0$. Then, Lemma 2 applies to the second equation in (62) and along any solution, $\overline{\text{sat}_\delta}$ desaturates after some time and the solution then satisfies:

$$\begin{cases} \dot{x} &= My \\ \dot{y} &= -k_1 \text{sat}_\delta(x) - k_2 y \\ &\quad -k_1 [\text{sat}_\delta(z) - \text{sat}_\delta(x)] + R\tilde{\mu} \\ \dot{z} - \dot{x} &= -k_3(z - x) - My \end{cases} \quad (63)$$

Note that System (63) is equivalent to System (45) when $z = x$ and $\tilde{\mu} = 0$. Consider the CLF V_1 defined by

$$V_1(x, y, z) = V(x, y) + (z - x)^2 \quad (64)$$

We deduce from the mean-value inequality and (2) that $|\text{sat}_\delta(z) - \text{sat}_\delta(x)| \leq C_\delta |z - x| \forall (z, x)$. Therefore, the time-derivative \dot{V}_1 of V_1 along the solutions of (63) satisfies:

$$\begin{cases} \dot{V}_1 \leq -C_{3,1} |y|^2 - C_{3,2} |z - x|^2 - C_{3,3} s_\delta^2 (|x|^2) |x|^2 \\ \quad + C_{3,4} |y| |z - x| + C_{3,5} |y| s_\delta (|x|^2) |x| \\ \quad + C_{3,6} |z - x| s_\delta (|x|^2) |x| + \frac{\partial V}{\partial y} R\tilde{\mu} \\ C_{3,1} := C_{1,1}, \quad C_{3,2} := 2k_3, \quad C_{3,3} := C_{1,3} \\ C_{3,4} := 2(C_\delta k_1 + 1) |M|_s, \quad C_{3,5} := C_{1,2}, \quad C_{3,6} := bC_\delta k_1 \end{cases} \quad (65)$$

with the $C_{1,j}$'s given by (51).

Let us first assume that $\tilde{\mu} = 0$. We claim that V_1 is a Lyapunov function for a proper choice of κ and k_3 . Let $0 < \kappa < \min\{\kappa_1, \kappa_2\}$ with κ_1, κ_2 defined by (47). From the proof of Prop. 1, $\kappa < \kappa_1$ implies that V is positive definite and proper, so that V_1 is positive definite and proper too. Then, $0 < \kappa < \kappa_2$ implies that $C_{3,1} > 0$. Since $C_{3,2}, C_{3,3} > 0$ and \dot{V}_1 is a quadratic form in $|y|, |z - x|$, and $s_\delta^2 (|x|^2) |x| = |\text{sat}_\delta(x)|$, \dot{V}_1 is negative definite provided that

$$4C_{3,1} C_{3,2} C_{3,3} > C_{3,1} C_{3,6}^2 + C_{3,2} C_{3,5}^2 + C_{3,3} C_{3,4}^2 + \frac{1}{2} C_{3,4} C_{3,5} C_{3,6} \quad (66)$$

This condition is satisfied by a proper choice of κ and k_3 . Indeed, the only term depending on k_3 in (66) is $C_{3,2}$. Thus, (66) is satisfied for k_3 large enough provided that $4C_{3,1} C_{3,3} > C_{3,5}^2$.

From (65), this is equivalent to $4C_{1,1}C_{1,3} > C_{1,2}^2$. This inequality, which corresponds to Condition c) in (52), is satisfied for $\kappa > 0$ small enough.

Let us now take into account the additive perturbation $\tilde{\mu}$. It follows from (65) and (66) that for some $\beta > 0$,

$$\dot{V}_1 \leq -\beta(|y|^2 + |z - x|^2 + |\text{sat}_\delta(x)|^2) + \left| \frac{\partial V}{\partial y} \right| |\tilde{\mu}| \quad (67)$$

and from (46), there exists $c > 0$ such that

$$\left| \frac{\partial V}{\partial y}(x, y) \right| \leq c|y, \text{sat}_\delta(x)| \quad \forall (x, y) \quad (68)$$

Therefore, by the triangular inequality,

$$\dot{V}_1 \leq -\frac{\beta}{2} \left(|y|^2 + |z - x|^2 + |\text{sat}_\delta(x)|^2 \right) + \frac{c^2 |\tilde{\mu}|^2}{2\beta}$$

Convergence to zero of V_1 then follows from the convergence of $\tilde{\mu}$ to zero. This, together with Lemma 3 implies the convergence of (p, \dot{p}, q, η) to $(p_r, \dot{p}_r, q_r, 0)$ from any initial condition in \mathcal{A} . Finally, local exponential stability follows from local exponential stability of $\tilde{\mu} = 0$ (Lemma 3) and the fact that saturation functions are identity functions around the origin (i.e., System (62) is locally linear).

Property ii): Lemma 3 still implies that $\tilde{\mu}$ exponentially converges to zero. Proceeding as in the proof of Prop. 1-ii), one deduces from Lemma 2 that for any $t \geq \bar{T}_\rho := \max_{|y| \leq \rho} T(y)$ and along any solution starting from \mathcal{A}_ρ , sat_δ desaturates and the solution satisfies

$$\begin{cases} \dot{x} &= My + \dot{M}\tilde{p} \\ \dot{y} &= -k_1 \text{sat}_\delta(x) - k_2 y \\ &\quad -k_1 [\text{sat}_\delta(z) - \text{sat}_\delta(x)] + R\tilde{\mu} \\ \dot{z} - \dot{x} &= -k_3(z - x) - My - \dot{M}\tilde{p} \end{cases} \quad (69)$$

Note that System (69) is equivalent to System (54) when $z = x$ and $\tilde{\mu} = 0$. Since $\tilde{\mu}$ exponentially converges to zero and $|\tilde{\mu}(0)| \leq |\mu(0)| \leq 2g + k_1 \delta_M + k_2 \delta_M$, there exists $T_1 > 0$ such that, for any initial condition in \mathcal{A}_ρ ,

$$|\tilde{\mu}(t)| \leq \frac{\beta \delta_m}{c \sqrt{6}}, \quad \forall t \geq T_1 \quad (70)$$

with β satisfying (67). Thus, for $t \geq \bar{T}_\rho := \max\{T_\rho, T_1\}$, both (69) and (70) are satisfied. Proceeding as in the proof of Prop. 1-ii), one also deduces from (55) that for some $\bar{\rho}$ and along any solution with initial condition in \mathcal{A}_ρ , $|(x(\bar{T}_\rho), y(\bar{T}_\rho), (z - x)(\bar{T}_\rho))| \leq \rho_1$. Let $\bar{\rho} := \max\{\rho_1, \delta_m\}$ so that $|(x(\bar{T}_\rho), y(\bar{T}_\rho), (z - x)(\bar{T}_\rho))| \leq \bar{\rho}$. We consider again the CLF V_1 defined by (64) and define s_m, x_M, V_M as follows (compare with (58)):

$$\begin{aligned} V_M &:= \max_{|(x,y,z-x)| \leq \bar{\rho}} V_1(x, y, z) > 0 \\ x_M &:= \max_{V_1(x,y,z) \leq V_M} |x| > 0 \\ s_m &:= \min_{|x| \leq x_M} s_\delta(|x|^2) > 0 \end{aligned} \quad (71)$$

By using (59), one deduces from (69) that for $|x| \leq x_M$ and for M such that $|\dot{M}|_s < \vartheta$,

$$\begin{aligned} \dot{V}_1 &\leq -C_{4,1}|y|^2 - C_{4,2}|z - x|^2 - C_{4,3}\text{sat}_\delta^2(|x|^2)|x|^2 \\ &\quad + C_{4,4}|y||z - x| + C_{4,5}|y|\text{sat}_\delta(|x|^2)|x| \\ &\quad + C_{4,6}|z - x|\text{sat}_\delta(|x|^2)|x| + \frac{\partial V}{\partial y} R\tilde{\mu} \end{aligned}$$

with:

$$\begin{cases} C_{4,1} := C_{3,1} - \vartheta, C_{4,2} := C_{3,2} \\ C_{4,3} := C_{3,3} - \frac{2k_1}{s_m |M|_s} \vartheta, C_{4,4} := C_{3,4} \\ C_{4,5} := C_{3,5} + \left[2 \frac{k_1}{k_2} + \left(2 \frac{k_1}{k_2} |M|_s + \kappa \right) \frac{C_\delta}{s_m |M|_s} \right] \vartheta \\ C_{4,6} := C_{3,6} + \frac{\vartheta}{s_m |M|_s} \end{cases}$$

Let us choose κ and k_3 as in the proof of case i) above, so that (66) is satisfied. Since the $C_{4,j}$'s tend to the $C_{3,j}$'s as ϑ tends to zero, for $\vartheta > 0$ small enough the following inequality is satisfied (compare with (67)):

$$\dot{V}_1 \leq -\frac{2\beta}{3}(|y|^2 + |z - x|^2 + |\text{sat}_\delta(x)|^2) + \left| \frac{\partial V}{\partial y} \right| |\tilde{\mu}| \quad (72)$$

Therefore, by (68) and the triangular inequality,

$$\dot{V}_1 \leq -\frac{\beta}{6} \left(|y|^2 + |z - x|^2 + |\text{sat}_\delta(x)|^2 \right) + \frac{c^2 |\tilde{\mu}|^2}{2\beta} \quad (73)$$

Recall that this relation is true as long as $|x(t)| \leq x_M$ and $t \geq \bar{T}_\rho$. In particular, it is true at $t = \bar{T}_\rho$ because $|(x(\bar{T}_\rho), y(\bar{T}_\rho), (z - x)(\bar{T}_\rho))| \leq \bar{\rho}$ (see above) and from (71),

$$|(x, y, z - x)| \leq \bar{\rho} \implies V_1(x, y, z) \leq V_M \implies |x| \leq x_M$$

From (73) and (70), $|x(t)| \leq x_M$ and $t \geq \bar{T}_\rho$ imply that

$$\dot{V}_1 \leq -\frac{\beta}{6} \left(|y|^2 + |z - x|^2 + |\text{sat}_\delta(x)|^2 - \frac{\delta_m^2}{2} \right) \quad (74)$$

We claim that

$$V_1(x, y, z) = V_M \implies |(x, y, z - x)| \geq \delta_m \quad (75)$$

Indeed, otherwise, from the definition of V_M in (71) and the fact that $\bar{\rho} \geq \delta_m$, on the set $\{(x, y, z) : |(x, y, z - x)| \leq \bar{\rho}\}$ V_1 reaches its maximum in the interior of this set, which implies that V_1 has a critical point. This contradicts (72) that implies V_1 is a Lyapunov function for $\tilde{\mu} = 0$.

From (71), $V_1 = V_M$ implies that $|x| \leq x_M$ and thus, (74) holds true. We thus deduce from (74), (75), and the properties of the function sat_δ that for any $t \geq \bar{T}_\rho$, $V_1 = V_M \implies \dot{V}_1 \leq -\frac{\beta \delta_m^2}{6} < 0$. Since $V_1 \leq V_M$ at $t = \bar{T}_\rho$, $V_1 \leq V_M$ everafter and thus, $|x| \leq x_M$ everafter. Then, (73) is satisfied for any $t \geq \bar{T}_\rho$ and convergence to zero of x, y, z follows from the convergence of $\tilde{\mu}$ to zero. Local exponential stability is deduced as for Property i). \blacksquare

Proof of Proposition 3: Let $x = R\tilde{\sigma}$, $y = R\tilde{v}$, $Y = (\mu_1, \mu_2)^T$, and $\varepsilon = \frac{1}{k_4}$. One obtains in closed-loop, after some calculations:

$$\begin{cases} \dot{x} &= My + \dot{M}\tilde{p} \\ \dot{y} &= -k_1 \text{sat}_\delta(x) - k_2 \overline{\text{sat}}_\delta(y) + R(Y_1, Y_2, 0)^T \\ \varepsilon \dot{Y} &= -\mu_3 Y + \varepsilon \omega_3(t) Y^\perp \\ &\quad + \varepsilon R_{1,2}^T (k_1 F_\delta(x) \dot{x} + k_2 \bar{F}_\delta(y) \dot{y}) \end{cases} \quad (76)$$

with $Y^\perp = (Y_2, -Y_1)^T$, $R_{1,2}^T$ the first two lines of R^T , and

$$\begin{cases} F_\delta(x) &:= s_\delta(|x|^2)I + 2s'_\delta(|x|^2)xx^T \\ \bar{F}_\delta(y) &:= \bar{s}_\delta(|y|^2)I + 2\bar{s}'_\delta(|y|^2)yy^T \end{cases} \quad (77)$$

Property i): It relies on the following lemma.

Lemma 4 Assume **A1**, **A2**, and **A3**. Then, for any $\rho > 0$ there exists $\varepsilon_\rho, T > 0$ such that, for any $\varepsilon \in (0, \varepsilon_\rho)$, any $t \geq T$, and along any solution of the system with initial condition in \mathcal{A}_ρ :

- a) $|y(t)| \leq \bar{\delta}_m$ (i.e. the function $\overline{\text{sat}}_\delta$ desaturates);
- b) $\mu_3(t) > g\kappa/\sqrt{2}$.

Lemma 4 implies that by choosing ε small enough, along any trajectory with initial condition in \mathcal{A}_ρ , the function $\overline{\text{sat}}_\delta$ desaturates after some time, so that the trajectory becomes solution to the system

$$\begin{cases} \dot{x} &= My \\ \dot{y} &= -k_1 \text{sat}_\delta(x) - k_2 y + R(Y_1, Y_2, 0)^T \\ \varepsilon \dot{Y} &= -\mu_3 Y + \varepsilon \omega_3(t) Y^\perp \\ &\quad + \varepsilon R_{1,2}^T (k_1 F_\delta(x) \dot{x} + k_2 \bar{F}_\delta(y) \dot{y}) \end{cases} \quad (78)$$

The first two equations of this system correspond to (45), modulo the additional term $R(Y_1, Y_2, 0)^T$. Then, using (53), property b) of Lemma 4, and (68), one deduces that $V_2(x, y, Y) := V(x, y) + |Y|^2$ is a Lyapunov function for System (78) for ε small enough, with \dot{V} upper-bounded by a negative definite quadratic function of $\text{sat}_\delta(x)$, y , and Y .

Property ii): It relies on the following lemma.

Lemma 5 Assume **A1** and **A2**. Then, for any $\rho > 0$ there exist $\varepsilon_\rho, T_0, \bar{c}_5, \beta, c, \vartheta > 0$ such that, for any $\varepsilon \in (0, \varepsilon_\rho)$, any $t \geq T_0$, any M such that $|\dot{M}|_s < \vartheta$, and along any solution of the system with initial condition in \mathcal{A}_ρ :

- a) $|x(t)| \leq \bar{c}_5$;
- b) $|y(t)| \leq \bar{\delta}_m$ (i.e. the function $\overline{\text{sat}}_\delta$ desaturates);
- c) $\mu_3(t) > g\kappa/\sqrt{2}$;
- d) $\dot{V} \leq -\frac{\beta}{2} |y, \text{sat}_\delta(x)|^2 + c |y, \text{sat}_\delta(x)| |Y|$, with V defined by (46).

Lemma 5 implies that by choosing ε and ϑ small enough, along any trajectory with initial condition in \mathcal{A}_ρ , the function $\overline{\text{sat}}_\delta$ desaturates after time T_0 , so that the trajectory becomes solution to the system

$$\begin{cases} \dot{x} &= My + \dot{M}\bar{p} \\ \dot{y} &= -k_1 \text{sat}_\delta(x) - k_2 y + R(Y_1, Y_2, 0)^T \\ \varepsilon \dot{Y} &= -\mu_3 Y + \varepsilon \omega_3(t) Y^\perp \\ &\quad + \varepsilon R_{1,2}^T (k_1 F_\delta(x) \dot{x} + k_2 \bar{F}_\delta(y) \dot{y}) \end{cases} \quad (79)$$

The first two equations of this system correspond to (54), modulo the term $R(Y_1, Y_2, 0)^T$. Property a) of Lemma 5 implies that x is bounded, so that $|(\dot{x}, \dot{y})|$ is bounded by a linear function of $|y|$, $|\text{sat}_\delta(x)|$, and $|Y|$ (see (59)). From here, Properties c) and d) of Lemma 4 and boundedness of F_δ, \bar{F}_δ imply that $V_2(x, y, Y) := V(x, y) + |Y|^2$ is a Lyapunov function for System (79) for ε small enough. ■

Proof of Proposition 4: Let $\bar{e}_\sigma := Re_\sigma = R\hat{\sigma} - M\bar{p}$, $\bar{e}_v := Re_v = R\hat{v}_M - M\bar{p}$. From (30)-(31), $\dot{\bar{e}}_\sigma = \bar{e}_v - 2\alpha k \bar{e}_\sigma$ and $\dot{\bar{e}}_v = -k^2 \bar{e}_\sigma - M\bar{p}$. Thus, e_σ is solution to a Hurwitz-stable second order linear equation with bounded input $u_b := -M\bar{p}$, i.e., $\ddot{\bar{e}}_\sigma + 2\alpha k \dot{\bar{e}}_\sigma + k^2 \bar{e}_\sigma = u_b$. Let $\tau := kt$ and ' denote the derivative w.r.t. τ . Then, the previous equation becomes $\bar{e}_\sigma'' + 2\alpha \bar{e}_\sigma' + \bar{e}_\sigma = \frac{u_b}{k^2}$. Since u_b is bounded, this implies the ultimate boundedness of

$|\bar{e}_\sigma|$ and $|\bar{e}_\sigma'|$ by a value proportional to $1/k^2$. Hence, $|\bar{e}_\sigma|$ and $|\bar{e}_\sigma'|$ are ultimately bounded by a value proportional to $1/k^2$ and $1/k$ respectively. The same property holds for $|e_\sigma|$ and $|e_v|$. ■

Proof of Proposition 5: Let $x := R\bar{\sigma} = M\bar{p}$ and $y := M^{-1}Rv_M = \bar{p}$. Then, x, y satisfy the following equations:

$$\begin{cases} \dot{x} &= My \\ \dot{y} &= -k_1 \text{sat}_\delta(x) - k_2 \overline{\text{sat}}_\delta(My) \end{cases} \quad (80)$$

This is the same as (42), except for the presence of the matrix M in the term $\overline{\text{sat}}_\delta(My)$. This similitude allows one to duplicate the proof of Prop. 1 modulo minor adaptations detailed below.

Lemma 2, with $\overline{\text{sat}}_\delta(y)$ in (43) replaced by $\overline{\text{sat}}_\delta(My)$ and the desaturation condition (44) replaced by

$$|M\varrho(t)| \leq k_2 \bar{\delta}_m |M|_i - k_1 \delta_M |M|_s - c_\varrho, \quad \forall t \geq t_1 \quad (81)$$

still holds true to show that $\overline{\text{sat}}_\delta(My)$ desaturates. Indeed, $\bar{y} := My$ satisfies the equation

$$\dot{\bar{y}} = -k_1 M \text{sat}_\delta(x) - k_2 M \overline{\text{sat}}_\delta(\bar{y}) + M\varrho(t)$$

and the proof proceeds like for Lemma 2, by considering the Lyapunov function V_0 defined by $V_0(\bar{y}) = \frac{1}{2} |\bar{y}|^2$. The second inequality in (32) ensures that (81) is satisfied with $\varrho \equiv 0$ and some $c_\varrho > 0$. After desaturation, solutions to (80) satisfy the following equations (compare with (45)):

$$\begin{cases} \dot{x} &= My \\ \dot{y} &= -k_1 \text{sat}_\delta(x) - k_2 My \end{cases} \quad (82)$$

The Lyapunov function in (46) is modified as follows:

$$\begin{aligned} V(x, y) &= k_1 \int_0^{|x|^2} s_\delta(\tau) d\tau + y^T My \\ &\quad + \frac{2k_1}{k_2} \text{sat}_\delta(x)^T M_a M^{-1} y + \kappa \text{sat}_\delta(x)^T y \end{aligned} \quad (83)$$

i.e., V so defined only differs from (46) by the matrix term $M_a M^{-1}$ (in place of M_a). We show that V is a Lyapunov function for κ small enough. Let (compare with (47))

$$\begin{cases} \bar{\kappa} &:= k_2^2 |M|_i^2 - k_1 |M_a M^{-1}|_s |M|_s C_\delta > 0 \\ \kappa_1 &:= 2\sqrt{k_1 |M|_i} - 2\frac{k_1}{k_2} |M_a M^{-1}|_s > 0 \\ \kappa_2 &:= \frac{2\bar{\kappa}}{k_2 |M|_s C_\delta} > 0 \\ \kappa_3 &:= \frac{\frac{2\bar{\kappa}}{k_2 |M|_s C_\delta}}{k_2 |M|_s C_\delta + \frac{k_3^2 |M|_i^2}{4k_1}} > 0 \\ 0 < \kappa &< \min\{\kappa_1, \kappa_2, \kappa_3\} \end{cases} \quad (84)$$

where positivity of $\bar{\kappa}, \kappa_1$ follows from (32) and positivity of κ_2, κ_3 is a consequence thereof. Positive definiteness of V is still ensured by (48), with b now defined by $b := \frac{2k_1}{k_2} |M_a M^{-1}|_s + \kappa$. This yields the condition $\kappa < \kappa_1$. Differentiating V along the solutions of System (82) yields

$$\begin{cases} \dot{V} = -2k_2 y^T M_s My + 2\frac{k_1}{k_2} y^T (M_a M^{-1})^T F_\delta(x) My \\ \quad - \kappa k_1 s_\delta^2(|x|^2) |x|^2 + \kappa y^T F_\delta(x) My \\ \quad - \kappa k_2 s_\delta(|x|^2) x^T My - 2\frac{k_1^2}{k_2} \text{sat}_\delta(x)^T M_a M^{-1} \text{sat}_\delta(x) \end{cases} \quad (85)$$

We now use the assumption that M_a and M_s commute. This implies that, for any $\xi \in \mathbb{R}^3$, $\xi^T M_s M_a \xi = 0$ and

$$\xi^T M_a M^{-1} \xi = ((M_a + M_s) M^{-1} \xi)^T M_a M^{-1} \xi = |M_a M^{-1} \xi|^2$$

Therefore, one deduces from (85) that

$$\begin{cases} \dot{V} \leq -2k_2|M_s y|^2 + 2\frac{k_1}{k_2}y^T(M_a M^{-1})^T F_\delta(x)My \\ -\kappa k_1 s_\delta^2(|x|^2)|x|^2 + \kappa y^T F_\delta(x)My \\ -\kappa k_2 s_\delta(|x|^2)x^T My \end{cases} \quad (86)$$

This implies that (50) is still satisfied with the $C_{1,j}$'s defined by (compare with (51))

$$C_{1,1} := 2k_2|M_i|^2 - b|M|_s C_\delta, \quad C_{1,2} := \kappa k_2|M|_s, \quad C_{1,3} := \kappa k_1$$

Thus, \dot{V} is negative definite provided that (52) is satisfied with the above-defined $C_{1,j}$'s. Condition a) follows from the fact that $\kappa < \kappa_2$. Condition b) holds true for any $\kappa > 0$ since $k_1 > 0$, and Condition c) follows from the fact that $\kappa < \kappa_3$. Thus, (53) is satisfied for some $\beta > 0$ and the end of the proof follows like for Proposition 1. \blacksquare

Proof of Proposition 6: Let $x := R\tilde{\sigma}$, $y := R\tilde{v}$, $Y := (\mu_1, \mu_2)^T$, and $\varepsilon := \frac{1}{k_4}$. One obtains in closed-loop, after some calculations (compare with (76) for $\dot{M} = 0$):

$$\begin{cases} \dot{x} = My \\ \dot{y} = -k_1 \text{sat}_\delta(x) - k_2 \overline{\text{sat}}_\delta(My) + R(Y_1, Y_2, 0)^T \\ \varepsilon \dot{Y} = -\mu_3 Y + \varepsilon \omega_3(t) Y^\perp \\ \quad + \varepsilon R_{1,2}^T (k_1 F_\delta(x) \dot{x} + k_2 \bar{F}_\delta(My) M \dot{y}) \end{cases} \quad (87)$$

with $Y^\perp = (Y_2, -Y_1)^T$, $R_{1,2}^T$ the first two lines of R^T , and F_δ, \bar{F}_δ defined by (77). By setting, like in the proof of Prop. 5, $\bar{y} := My = R^T v_M$, the above equations can also be written as

$$\begin{cases} \dot{x} = \bar{y} \\ \dot{\bar{y}} = -k_1 M \text{sat}_\delta(x) - k_2 M \overline{\text{sat}}_\delta(\bar{y}) + MR(Y_1, Y_2, 0)^T \\ \varepsilon \dot{Y} = -\mu_3 Y + \varepsilon \omega_3(t) Y^\perp \\ \quad + \varepsilon R_{1,2}^T (k_1 F_\delta(x) \dot{x} + k_2 \bar{F}_\delta(\bar{y}) \dot{\bar{y}}) \end{cases} \quad (88)$$

We claim that the conclusion of Lemma 4 is still valid with statement a) replaced by:

a) $|\bar{y}(t)| \leq \bar{\delta}_m$ (i.e. the function $\overline{\text{sat}}_\delta$ desaturates)

Indeed, based on (87) the proof follows exactly that of Lemma 4 with y replaced everywhere by \bar{y} , and the constant $k_2 \bar{\delta}_m - k_1 \delta_M$ in (102) and subsequent equations replaced everywhere by $k_2 \bar{\delta}_m |M|_i - k_1 \delta_M |M|_s$ (compare with (81)). Note also that the value of the constants c_1, c_2 must be changed as follows: $c_1 := k_1 \delta_M + k_2 \bar{\delta}_m + g$ (from (35)) and therefore, from (88), $c_2 := |M|_s (2k_1 \delta_M + 2k_2 \bar{\delta}_m + g)$.

After desaturation of the function $\overline{\text{sat}}_\delta$, the trajectories of System (87) become solution to the system

$$\begin{cases} \dot{x} = My \\ \dot{y} = -k_1 \text{sat}_\delta(x) - k_2 My + R(Y_1, Y_2, 0)^T \\ \varepsilon \dot{Y} = -\mu_3 Y + \varepsilon \omega_3(t) Y^\perp \\ \quad + \varepsilon R_{1,2}^T (k_1 F_\delta(x) \dot{x} + k_2 \bar{F}_\delta(My) M \dot{y}) \end{cases} \quad (89)$$

The first two equations in (89) correspond to (82) modulo the additional term $R(Y_1, Y_2, 0)^T$. The end of proof follows as for Prop. 3, using the fact that V in (83) satisfies (53). \blacksquare

Proof of Lemmas

Proof of Lemma 1: We proceed by contradiction. Assume that $\mu(0) = -|\mu(0)|e_3$. From (20) and (23) $\mu(0) \neq 0$. From (20), $\gamma(0) + |\mu(0)|e_3 = -(k_1 \text{sat}_\delta(\eta) + k_2 \overline{\text{sat}}_\delta(\tilde{v}) - a_r)$. Thus,

$$\begin{aligned} |k_1 \text{sat}_\delta(\eta) + k_2 \overline{\text{sat}}_\delta(\tilde{v}) - a_r|^2 &= |\gamma(0) + |\mu(0)|e_3|^2 \\ &= |\gamma(0)|^2 + |\mu(0)|^2 + 2|\mu(0)|\gamma_3(0) \\ &= g^2 + |\mu(0)|^2 + 2|\mu(0)|\gamma_3(0) \\ &> g^2 + |\mu(0)|^2 - 2|\mu(0)|\sqrt{g^2 - (k_1 \delta_M + k_2 \bar{\delta}_M + |\dot{p}_{r|s})^2} \\ &> (k_1 \delta_M + k_2 \bar{\delta}_M + |\dot{p}_{r|s})^2 \\ &\quad + \left(\sqrt{g^2 - (k_1 \delta_M + k_2 \bar{\delta}_M + |\dot{p}_{r|s})^2} - |\mu(0)| \right)^2 \\ &> (k_1 \delta_M + k_2 \bar{\delta}_M + |\dot{p}_{r|s})^2 \end{aligned}$$

where the first inequality comes from (24) and the fact that $\mu(0) \neq 0$. This contradicts (23). \blacksquare

Proof of Lemma 2: Consider the function V_0 defined by $V_0(y) = \frac{1}{2}|y|^2$. Its derivative along the solutions of Eq. (43) is given by

$$\begin{aligned} \dot{V}_0 &= -k_1 y^T \text{sat}_\delta(x) - k_2 y^T \overline{\text{sat}}_\delta(y) + y^T \varrho(t) \\ &\leq k_1 |y| \delta_M - k_2 y^T \overline{\text{sat}}_\delta(y) + |y| |\varrho(t)| \end{aligned} \quad (90)$$

Case 1: $t \in [0, t_1]$. Let $|\varrho|_s$ denote the max of ϱ on this time interval. From the above inequality,

$$\dot{V}_0 \leq k_1 |y| \delta_M + |y| |\varrho|_s \leq (k_1 \delta_M + |\varrho|_s) \sqrt{2V_0}$$

The comparison lemma Khalil (2002) then yields

$$|y(t_1)| \leq |y(0)| + (k_1 \delta_M + |\varrho|_s) t_1 \quad (91)$$

Case 2: $t \geq t_1$. From Def. 1,

$$\begin{aligned} |y| \geq \bar{\delta}_m &\implies y^T \overline{\text{sat}}_\delta(y) = |y|^2 \bar{s}_\delta(|y|^2) = |y| \bar{s}_\delta(|y|^2) |y| \\ &\geq |y| \bar{s}_\delta(\bar{\delta}_m^2) \bar{\delta}_m \geq |y| \bar{\delta}_m \end{aligned}$$

Therefore, from (90),

$$\begin{aligned} |y(t)| \geq \bar{\delta}_m &\implies \dot{V}_0(t) \leq -(k_2 \bar{\delta}_m - k_1 \delta_M - |\varrho(t)|) |y| \\ &\implies \dot{V}_0(t) \leq -c_\varrho \sqrt{2V_0} \end{aligned}$$

where the last inequality comes from (44). We deduce from this inequality that

1. If $|y(t_1)| \leq \bar{\delta}_m$ then $|y(t)| \leq \bar{\delta}_m$ for any $t \geq t_1$;
2. If $|y(t_1)| > \bar{\delta}_m$ then, by application of the comparison lemma to the above inequality, $|y(t)| \leq \bar{\delta}_m$ for any $t \geq t_1 + \frac{|y(t_1)| - \bar{\delta}_m}{c_\varrho}$.

Then, it follows from (91) that $|y(t)| \leq \bar{\delta}_m$ for any $t \geq T(y(0)) := t_1 + \max\{0, \frac{|y(0)| + (k_1 \delta_M + |\varrho|_s) t_1 - \bar{\delta}_m}{c_\varrho}\}$. In other words, $\overline{\text{sat}}_\delta(y(t)) = y(t)$ for $t \geq T(y(0))$. \blacksquare

Proof of Lemma 3: It relies on the following result (Hua et al., 2009, Prop. 1)

Proposition 7 Consider a smooth function ζ with $|\zeta| = 1$ and $\dot{\zeta}$ independent of ω . Let $\bar{\zeta} := R^T \zeta$ and

$$\begin{cases} \omega_1 &= -k_4 \frac{\bar{\zeta}_2}{(1+\bar{\zeta}_3)^2} - \zeta^T S(Re_1) \dot{\zeta} \\ \omega_2 &= k_4 \frac{\bar{\zeta}_1}{(1+\bar{\zeta}_3)^2} - \zeta^T S(Re_2) \dot{\zeta}, \quad k_4 > 0 \end{cases} \quad (92)$$

Then, on the unit sphere, $Re_3 = \zeta$ is exponentially stable with convergence domain $\{R(0)e_3 : \zeta^T(0)R(0)e_3 \neq -1\}$.

We apply the above proposition with $\zeta := \frac{R\mu}{|\mu|}$. First, ζ is well defined because, from (20) and (23), μ never vanishes. Then, ζ is a smooth function since both R and μ are smooth. Let us check that $\dot{\zeta}$ is independent of ω . First, recall that by Def. 1-i), $R\text{sat}(z) = \text{sat}(Rz)$ for any R, z . Therefore, from (20) and the definitions of γ, \bar{v} , and a_r ,

$$\zeta = \frac{ge_3 + k_1 \text{sat}_\delta(R\eta) + k_2 \overline{\text{sat}}_\delta(\bar{p}) - \bar{p}_r}{|ge_3 + k_1 \text{sat}_\delta(R\eta) + k_2 \overline{\text{sat}}_\delta(\bar{p}) - \bar{p}_r|}$$

The derivatives of $ge_3, k_2 \overline{\text{sat}}_\delta(\bar{p})$ and \bar{p}_r do not depend on ω . As for $R\eta$, it follows from (6) and (18) that $\frac{d}{dt}(R\eta) = -k_3(R\eta - M\bar{p})$. This term is thus also independent of ω . Thus $\dot{\zeta}$ is independent of ω .

By replacing ζ in (92) by the expression $\zeta := \frac{R\mu}{|\mu|}$, one obtains after a few calculation the expression (19). By application of Prop. 7, we deduce that $Re_3 = \zeta$ is exponentially stable with convergence domain $\{R : \zeta^T(0)R(0)e_3 \neq -1\}$. Thus, $\exists c, \alpha > 0 : |Re_3 - \zeta| \leq c|(Re_3 - \zeta)(0)|e^{-\alpha t}, \forall t$. This is equivalent to $|e_3 - \frac{\mu}{|\mu|}| \leq c|(e_3 - \frac{\mu}{|\mu|})(0)|e^{-\alpha t}, \forall t$. Since, from A1, (20), and (23), $|\mu|$ is lower and upper-bounded by strictly positive constants independent of the initial conditions, the above inequality is equivalent to $|\bar{\mu}(t)| \leq \bar{c}|\bar{\mu}(0)|e^{-\alpha t}$ for some constant \bar{c} . ■

Proof of Lemma 4: Since $\mathcal{A}_{\rho^*} \subset \mathcal{A}_\rho$ when $\rho^* < \rho$, it is sufficient to prove the existence of $\varepsilon_\rho > 0$ for any $\rho > \rho^*$, where ρ^* is any strictly positive value. Thus, we assume from now on that

$$\rho > \bar{\delta}_m \quad (93)$$

Let us first establish a few inequalities. From (25) and (27), $|Y|^2 + \mu_3^2 = |\mu|^2 > g^2 \varkappa^2$. Thus,

$$\forall t \geq 0, \quad \mu_3(t)^2 > g^2 \varkappa^2 - |Y(t)|^2 \quad (94)$$

From (27) and Assumption A3,

$$|\mu| < c_1 := k_1 \delta_M + k_2 \bar{\delta}_M + 2g \quad (95)$$

Therefore, $|Y| = |(\mu_1, \mu_2)^T| < c_1$ and from (76),

$$|y| < c_2 := 2(k_1 \delta_M + k_2 \bar{\delta}_M + g) \quad (96)$$

Recalling that $y = R\bar{v}$, it follows from (28) and (96) that

$$\forall t > 0, \quad |y(t)| < \rho + c_2 t \quad (97)$$

Since M is constant, (76) implies that $\dot{x} = My$. Recalling, from (2), that F_δ and \bar{F}_δ are bounded by C_δ , it follows from (76) that

$$\varepsilon \dot{Y} = -\mu_3 Y + \varepsilon \omega_3(t) Y^\perp + \varepsilon (\xi_1 + \xi_2 y) \quad (98)$$

where ξ_1, ξ_2 are functions bounded by a constant c_3 independent of ε . Thus, using the triangular inequality,

$$\frac{d}{dt}|Y|^2 \leq |Y|^2 \left(-\frac{2\mu_3}{\varepsilon} + 1 \right) + c_3^2(1 + |y|^2) \quad (99)$$

Let T_0 denote any strictly positive constant. It follows from (97) and (99) that

$$\forall t \in [0, T_0], \quad \frac{d}{dt}|Y|^2(t) \leq |Y|^2(t) \left(-\frac{2\mu_3(t)}{\varepsilon} + 1 \right) + c_4 \quad (100)$$

with

$$c_4 := c_3^2(1 + (\rho + c_2 T_0)^2) \quad (101)$$

We show that there exists $\varepsilon_0 > 0$ such that, for any $\varepsilon \leq \varepsilon_0$ and any initial condition in \mathcal{A}_ρ ,

$$|Y(T_0)| < \bar{\varepsilon} := \min \left\{ \frac{9(k_2 \bar{\delta}_m - k_1 \delta_M)}{10}, g\varkappa/\sqrt{2} \right\} \quad (102)$$

We claim that there exists $\bar{\varepsilon}_1 > 0$ such that, $\forall \varepsilon \leq \bar{\varepsilon}_1$,

$$\forall t \in [0, T_0], \quad |Y(t)|^2 < g^2 \varkappa^2 / 2 \quad (103)$$

Suppose on the contrary that there exists a sequence $(\varepsilon_n)_{n>0}$ converging to zero such that, for any $\varepsilon = \varepsilon_n$ there exists a time $\bar{t}_n \in [0, T_0]$ such that $|Y(\bar{t}_n)|^2 \geq g^2 \varkappa^2 / 2$. Since, from (28), $|Y(0)|^2 < g^2 \varkappa^2 / 2$, we can assume without loss of generality that $|Y(t)|^2 \leq |Y(\bar{t}_n)|^2 = g^2 \varkappa^2 / 2$ for $t \leq \bar{t}_n$. Therefore,

$$\frac{d}{dt}|Y|^2(\bar{t}_n) \geq 0 \quad (104)$$

On the other hand, from (94), the fact that $\mu_3(0) > 0$ (cf. (28)), and the fact that $|Y(t)|^2 \leq g^2 \varkappa^2 / 2$ for $t \leq \bar{t}_n$, we deduce that $\mu_3(\bar{t}_n) > g\varkappa/\sqrt{2}$. Thus, we deduce from (100) and (104) that

$$0 \leq \frac{g^2 \varkappa^2}{2} \left(-\frac{2\mu_3(\bar{t})}{\varepsilon} + 1 \right) + c_4 < \frac{g^2 \varkappa^2}{2} \left(-\frac{\sqrt{2}g\varkappa}{\varepsilon} + 1 \right) + c_4$$

This is impossible if $\varepsilon < \bar{\varepsilon}_1 := g^3 \varkappa^3 \sqrt{2} / (g^2 \varkappa^2 + 2c_4)$, which shows (103) for $\varepsilon \leq \bar{\varepsilon}_1$. From (103), (94), and the fact that $\mu_3(0) > 0$, it follows that $\mu_3(\bar{t}) > g\varkappa/\sqrt{2}$ for all $t \in [0, T_0]$. In other words, for $\varepsilon \leq \bar{\varepsilon}_1$,

$$\forall t \in [0, T_0], \quad |Y(t)|^2 < g^2 \varkappa^2 / 2, \quad \mu_3(t) > g\varkappa/\sqrt{2} \quad (105)$$

Therefore, from (100),

$$\forall t \in [0, T_0], \quad \frac{d}{dt}|Y|^2(t) \leq |Y|^2(t) \left(-\frac{g\varkappa\sqrt{2}}{\varepsilon} + 1 \right) + c_4$$

Applying the comparison lemma yields

$$\forall t \in [0, T_0], \quad |Y|^2(t) \leq e^{-at} \left(|Y|^2(0) - \frac{c_4}{a} \right) + \frac{c_4}{a} \quad (106)$$

with $a = \frac{g\varkappa\sqrt{2}}{\varepsilon} - 1$. Since a tends to infinity as ε tends to zero and $|Y(0)| < g\varkappa/\sqrt{2}$, there exists $\bar{\varepsilon}_2$ such that, $\forall \varepsilon \leq \bar{\varepsilon}_2$,

$$e^{-aT_0} \left(|Y|^2(0) - \frac{c_4}{a} \right) + \frac{c_4}{a} < \left(\frac{9(k_2 \bar{\delta}_m - k_1 \delta_M)}{10} \right)^2$$

This inequality, together with (106) and (103) imply (102) for $\varepsilon \leq \varepsilon_0 := \min\{\bar{\varepsilon}_1, \bar{\varepsilon}_2\}$.

We now assume that

$$\varepsilon \in (0, \varepsilon_\rho) \text{ with } \varepsilon_\rho = \min \left\{ \varepsilon_0, \frac{\sqrt{2}g\kappa\bar{\varepsilon}^2}{\bar{\varepsilon}^2 + c_4} \right\} \quad (107)$$

We claim that

$$\forall t \geq T_0, \begin{cases} |y(t)| < \rho + c_2T_0 \\ |Y(t)| < \bar{\varepsilon} \\ \mu_3(t) > g\kappa/\sqrt{2} \end{cases} \quad (108)$$

Since $\varepsilon < \varepsilon_0$, it follows from (97), (102), and (105) that the three inequalities in (108) are satisfied at $t = T_0$. Suppose by contradiction that there exists $T > T_0$ such that at least one of the three inequalities in (108) is not satisfied at $t = T$ and these inequalities are satisfied for any $t \in [T_0, T)$. We distinguish three cases:

Case 1: $|y(T)| = \rho + c_2T_0$. We claim that

$$\forall t \in [T_0, T), \quad |y(t)| \leq \max\{\bar{\delta}_m, |y(T_0)|\} \quad (109)$$

Indeed, from (108) for $t \in [T_0, T)$, $|Y(t)| \leq \bar{\varepsilon} < k_2\bar{\delta}_m - k_1\delta_M$ for any $t \in [T_0, T)$. Therefore, by (76),

$$\forall t \in [T_0, T), \quad |y(t)| \geq \bar{\delta}_m \implies \frac{d}{dt}|y(t)| < 0 \quad (110)$$

Thus, if $\max\{\bar{\delta}_m, |y(T_0)|\} = |y(T_0)|$ then $|y(t)| \leq |y(T_0)|$ for all $t \in [T_0, T)$, and if $\max\{\bar{\delta}_m, |y(T_0)|\} = \bar{\delta}_m$ then $|y(t)| \leq \bar{\delta}_m$ for all $t \in [T_0, T)$. This proves (109). By continuity, $|y(T)| \leq \max\{\bar{\delta}_m, |y(T_0)|\}$. This contradicts the assumption $|y(T)| = \rho + c_2T_0$ since $|y(T_0)| < \rho + c_2T_0$ by (97), and $\bar{\delta}_m < \rho$ by (93).

Case 2: $|Y(T)| = \bar{\varepsilon}$. Since (108) is satisfied for $t \in [T_0, T)$,

$$\frac{d}{dt}|Y|^2(T) \geq 0 \quad (111)$$

It follows from (99), (101), and (108) for $t < T$, that

$$\begin{aligned} \frac{d}{dt}|Y|^2(T) &\leq |Y|^2(T) \left(-\frac{g\kappa\sqrt{2}}{\varepsilon} + 1 \right) + c_4 \\ &\leq \bar{\varepsilon}^2 \left(-\frac{g\kappa\sqrt{2}}{\varepsilon} + 1 \right) + c_4 < 0 \end{aligned} \quad (112)$$

where the last inequality follows from (107). This contradicts (111).

Case 3: $\mu_3(T) = g\kappa/\sqrt{2}$. Since (108) is satisfied for $t < T$, it follows by continuity that $|Y(T)|^2 \leq g^2\kappa^2/2$. Thus, $\mu_3(T)^2 + |Y(T)|^2 \leq g^2\kappa^2$, which contradicts (94).

This concludes the proof of (108). Lemma 4 follows from (108) and Lemma 2 applied to the second equation in (76) with $\varrho(t) = R(t)(Y_1(t), Y_2(t), 0)^T$. ■

Proof of Lemma 5: It is inspired by the proof of Lemma 4. Let us first define some constant numbers. With c_2 defined by (96) and V given by (46) the Lyapunov function of Prop. 1, let us define

$$\begin{aligned} T_0 &:= \frac{\bar{\delta}_m}{2c_2}, \quad c_5 := \left(\rho + \frac{\bar{\delta}_m T_0}{2} + \frac{c_2 T_0^2}{2} \right) |M|_s \\ \bar{V} &:= \max\{|V(x, y)| : |x| \leq c_5, |y| \leq \bar{\delta}_m\} \\ \bar{c}_5 &:= \max\{|x| : \inf_y V(x, y) \leq 2\bar{V}\} \\ c_6 &:= \min\{|(y, \text{sat}_\delta(x))| : V(x, y) = 2\bar{V}\} \\ \bar{\varepsilon} &:= \min \left\{ \frac{9(k_2\bar{\delta}_m - k_1\delta_M)}{10}, \frac{g\kappa}{\sqrt{2}}, \frac{9}{10} \frac{\beta c_6}{2c} \right\} \end{aligned} \quad (113)$$

with c any constant satisfying (68). Note that \bar{c}_5 is well defined because V is proper. Note also, from the definition of \bar{V} and \bar{c}_5 , that

$$c_5 \leq \bar{c}_5 \quad (114)$$

Relations (94) to (96) are still valid when M is not constant. As for (97), using (29) it becomes

$$\forall t > 0, \quad |y(t)| < \frac{\bar{\delta}_m}{2} + c_2t \quad (115)$$

Due to the term $\dot{M}\tilde{p} = \dot{M}M^{-1}x$ in the expression (76) of \dot{x} , relation (98) becomes

$$\varepsilon\dot{Y} = -\mu_3Y + \varepsilon\omega_3(t)Y^\perp + \varepsilon(\xi_1 + \xi_2Y + \xi_3x) \quad (116)$$

with ξ_1, ξ_2, ξ_3 functions bounded by a constant c_3 independent of ε . Thus, by the triangular inequality (99) becomes

$$\frac{d}{dt}|Y|^2 \leq |Y|^2 \left(-\frac{2\mu_3}{\varepsilon} + 1 \right) + c_3^2(1 + |y|^2 + |x|^2) \quad (117)$$

Since $\dot{\tilde{p}} = R\tilde{v} = y$, $|\tilde{p}(t) - \tilde{p}(0)| \leq \int_0^t |y(s)| ds$ for all t . Thus, from (29) and (115), $|\tilde{p}(t)| < \rho + \frac{\bar{\delta}_m t}{2} + \frac{c_2 t^2}{2}$ for any $t > 0$, which implies by the definition (113) of c_5 that

$$\forall t \in (0, T_0], \quad |x(t)| < c_5 \leq \bar{c}_5 \quad (118)$$

where the last inequality comes from (114). We deduce from (115), (117), and (118) that (100) is satisfied with c_4 now defined by

$$c_4 := c_3^2(1 + \bar{\delta}_m^2 + \bar{c}_5^2) \quad (119)$$

From here, one can proceed as in the proof of Lemma 4 to show that for ε smaller than some $\varepsilon_0 > 0$, (102) and (105) hold true with $\bar{\varepsilon}$ defined by (113).

Recall from (113) that $T_0 := \frac{\bar{\delta}_m}{2c_2}$. Thus, from (115), $|y(T_0)| < \bar{\delta}_m$. We impose on ε the condition (107), with c_4 defined by (119). We claim that there exists $\vartheta > 0$ such that, provided that $|\dot{M}|_s \leq \vartheta$,

$$\forall t \geq T_0, \begin{cases} i) |V(x(t), y(t))| < 2\bar{V} & ii) |y(t)| < \bar{\delta}_m \\ iii) |Y(t)| < \bar{\varepsilon} & iv) \mu_3(t) > \frac{g\kappa}{\sqrt{2}} \end{cases} \quad (120)$$

The four properties in (120) are satisfied at $t = T_0$. Indeed, by (113), (115), and (118), $|V(x(T_0), y(T_0))| \leq \bar{V}$. Property *ii)*, at $t = T_0$, follows from (115). Properties *iii-iv)* follow from (102) and (105), which are satisfied because $\varepsilon < \varepsilon_0$. To prove (120) we proceed by contradiction. Suppose that for any $\vartheta > 0$ there exists some M with $|\dot{M}|_s \leq \vartheta$ and some $T > T_0$ such that at least one of the properties in (108) is not satisfied at $t = T$ and these properties are satisfied $\forall t \in [T_0, T)$. We distinguish four cases.

Case 1: $|V(x(T), y(T))| = 2\bar{V}$. Since (120) is satisfied for $t \in [T_0, T)$, one has

$$\dot{V}(x(T), y(T)) \geq 0 \quad (121)$$

One also deduces from (120) on the time-interval $[T_0, T)$ that on the time-interval $[T_0, T]$, the function sat_δ desaturates. Thus, from (76), the solution satisfies on $[T_0, T]$:

$$\begin{cases} \dot{x} &= My + \dot{M}\tilde{p} \\ \dot{y} &= -k_1 \text{sat}_\delta(x) - k_2y + R(Y_1, Y_2, 0)^T \end{cases} \quad (122)$$

This system corresponds to (54) modulo the additive "perturbation" $R(Y_1, Y_2, 0)^T$. It follows from (120) for $t \in [T_0, T]$ that $|V(x(T), y(T))| \leq 2\bar{V}$. From (113), this implies that $|x(t)| \leq \bar{c}_5 \forall t \in [T_0, T]$. Using the same argument as for (59), one deduces that $\forall t \in [T_0, T]$, $|x(t)| \leq \frac{|\text{sat}_\delta(x)|}{s_m}$ with $s_m := \min_{|x| \leq \bar{c}_5} s_\delta(|x|^2)$. With this definition of s_m , it follows from (60) that the derivative of V along the solutions of (122) satisfies, on the time-interval $[T_0, T]$:

$$\dot{V} \leq -C_{2,1}|y|^2 + C_{2,2}|y||\text{sat}_\delta(x)| - C_{2,3}|\text{sat}_\delta(x)|^2 + \frac{\partial V}{\partial y}R(Y_1, Y_2, 0)^T \quad (123)$$

with $C_{2,1}, C_{2,2}, C_{2,3}$ defined by (61). From (61), the coefficients $C_{2,j}$ tend to $C_{1,j}$ as ϑ tends to zero. Therefore, by (53) there exists $\vartheta > 0$ such that, for $|M|_s \leq \vartheta$,

$$\dot{V} \leq -\frac{\beta}{2}(|y|^2 + |\text{sat}_\delta(x)|^2) + \frac{\partial V}{\partial y}R(Y_1, Y_2, 0)^T \quad (124)$$

Using (68), we then deduce that

$$\dot{V} \leq -\frac{\beta}{2}(|y|^2 + |\text{sat}_\delta(x)|^2) + c|y, \text{sat}_\delta(x)||Y| \quad (125)$$

It thus follows from (120) for $t \in [T_0, T]$ that, on the time-interval $[T_0, T]$,

$$\dot{V} \leq -\frac{\beta}{2}(|y|^2 + |\text{sat}_\delta(x)|^2) + c\bar{\varepsilon}|y, \text{sat}_\delta(x)| \quad (126)$$

From (113) and the assumption $V(x(T), y(T)) = 2\bar{V}$, one deduces that $|y(T), \text{sat}_\delta(x(T))| \geq c_6$. Then, it follows from (126) and (113) that $\dot{V}(x(T), y(T)) < 0$. This contradicts (121).

Case 2: $|y(T)| = \bar{\delta}_m$. Since (120) is satisfied for $t \in [T_0, T]$, it follows that $\frac{d}{dt}|y|^2(T) \geq 0$. Since $|Y(t)| \leq \bar{\varepsilon}$ on $[T_0, T]$, relation (110) still holds, which implies that $\frac{d}{dt}|y|^2(T) < 0$, thus a contradiction.

Case 3: $|Y(T)| = \bar{\varepsilon}$. Since (120) is satisfied for $t \in [T_0, T]$, it follows that $\frac{d}{dt}|Y|^2(T) \geq 0$. Furthermore, (120) for $t < T$ and (113) imply that $x(T) \leq \bar{c}_5$. This implies, from (117) and (120) for $t < T$, that (112) is satisfied with c_4 defined by (119). We thus obtain a contradiction.

Case 4: $\mu_3(T) = g\varepsilon/\sqrt{2}$. One proceeds as in Case 3 of Lemma 4 to show that this case also yields a contradiction.

We thus have proved that (120) is satisfied if $\vartheta > 0$ is chosen small enough. Property a) of Lemma 5 follows from i) in (120) and (113). Properties b-c) correspond to ii-iii) in (120). Finally, since $|x(t)| \leq \bar{c}_5$, (125) is satisfied, which corresponds to Property d) of Lemma 5. ■
