ABSTRACT:

Rationale: Mechanisms underlying membrane protein localization are crucial in the proper function of cardiomyocytes. The main cardiac sodium channel, NaV1.5, carries the sodium current (I_{Na}) which provides a rapid depolarizing current during the upstroke of the action potential. While enriched in the intercalated disc (ID), NaV1.5 is present in different membrane domains in myocytes and interacts with several partners.

Objective: To test the hypothesis that the Membrane-Associated GUanylate Kinase (MAGUK) protein CAcium/calmodulin-dependent Serine protein Kinase (CASK) interacts with and regulates NaV1.5 in cardiomyocytes.

Methods and results: Immunostaining experiments showed that CASK localizes at lateral membranes (LM) of cardiomyocytes, in association with dystrophin. Whole-cell patch clamp showed that CASK-silencing increases I_{Na} in vitro. In vivo CASK knockdown similarly increased I_{Na} recorded in freshly isolated myocytes. Pull-down experiments revealed that CASK directly interacts with the C-terminus of NaV1.5. CASK silencing reduces syntrophin expression without affecting NaV1.5 and dystrophin expression levels. Total Internal Reflection Fluorescence microscopy (TIRFm) and biotinylation assays showed that CASK silencing increased the surface expression of NaV1.5 without changing mRNA levels. Quantification of NaV1.5 expression at the LM and ID revealed that the LM pool only was increased upon CASK silencing. The protein transport inhibitor brefeldin-A prevented I_{Na} increase in CASK-silenced myocytes. During atrial dilation/remodeling, CASK expression was reduced but its localization unchanged.

Conclusion: This study constitutes the first description of an unconventional MAGUK protein, CASK, which directly interacts with NaV1.5 channel and controls its surface expression at the LM by regulating ion channel trafficking.

Keywords: MAGUK, CASK, syntrophin, sodium channel, cardiomyocyte

- 3-D: 3-dimensionnal
- TIRFm: Total Internal Reflection Fluorescence microscopy
- shRNA: short hairpin RNA
- Ad: adenovirus
- DIV: Day in vitro
- BFA: brefeldin-A
INTRODUCTION

Cardiomyocytes are highly differentiated striated muscle cells possessing well-organized membrane domains with specialized roles in their electrical and mechanical functions. The T-tubule system and intercalated discs (ID) are the best characterized membrane domains and are crucial for the excitation-contraction (EC) coupling process and the propagation of action potentials (AP) from one myocyte to the other. Specialized membrane domains contain distinct populations of ion channels, pumps, exchangers and receptors such as the voltage-gated L-type calcium channel and gap-junctional protein connexin-43, for T-tubules and ID respectively.

The main cardiac Na\(_\text{v}1.5\) sodium channel is responsible for the sodium current \(I_{Na}\), which provides a rapid depolarizing current during the upstroke of the AP. Recent studies suggest the presence of distinct populations of Na\(_\text{v}1.5\) channel located in different specialized membrane domains of cardiomyocytes, as well as their association with specific partners. At the ID, Na\(_\text{v}1.5\) has been shown to be associated with gap junctional (connexin-43)\(^2\), desmosomal (plakophilin-2)\(^3,4\), actin cytoskeleton-binding (ankyrin-G)\(^5,6\), and Membrane-Associated GUanylate Kinase (MAGUK, SAP-97) proteins\(^7,8\).

The mechanisms regulating the spatial organization of ion channels are still poorly understood. Targeting and clustering of transmembrane proteins to cell junctions are critical for the organization of specialized membrane domains in structurally polarized cells such as neurons, epithelial cells or cardiomyocytes. MAGUK proteins have emerged as key partners participating in this organization\(^9\). For instance, in the central nervous system, MAGUK proteins organize synapses through their ability to establish specific macromolecular complexes. In cardiomyocytes, SAP-97 is a key regulator of ion channel function and organization\(^7,8,10-13\) whereas ZO-1 organizes the gap-junction protein connexin-43 at the ID\(^14\). Similar to other MAGUK proteins, CASK (Calcium/Calmodulin-dependent Serine Kinase) displays a multidomain structure enabling interaction with multiple proteins including ion channels and receptors, cell-adhesion proteins and the actin cytoskeleton\(^9\). However, among MAGUK proteins, CASK differs due to the possession of an active CaMKII homolog domain in the N-terminal and a GUK (guanylate-kinase) domain in its C-terminus which is involved in CASK translocation to the nucleus and subsequent regulation of gene expression\(^15\). Despite previous works reporting the expression of CASK in the myocardium\(^16,17\), its function has not been investigated. Therefore, we investigated the potential role of CASK in the regulation of Na\(_\text{v}1.5\) channels in cardiomyocytes.

Here we present the first detailed characterization of the localization and function of CASK in the heart. CASK was detected specifically in costameric structures of the lateral membrane (LM) of cardiomyocytes, in association with dystrophin. Using a combination of whole-cell patch-clamp, high resolution 3-dimensional deconvolution microscopy and biochemistry, we showed that CASK interacts with Na\(_\text{v}1.5\) and negatively regulates the corresponding current in cultured adult atrial myocytes. CASK knock down \textit{in vivo} revealed that CASK exerted the same regulatory function in freshly isolated ventricular myocytes. Pull down assays showed that CASK directly interacts with the C-terminus of Na\(_\text{v}1.5\). Biotinylation and Total Internal Reflection Fluorescence (TIRF) microscopy revealed that CASK silencing increased Na\(_\text{v}1.5\) expression at the cell surface without changing Na\(_\text{v}1.5\) mRNA and protein levels. However, CASK silencing reduced the expression of syntrophin. The \(I_{Na}\) increase induced by CASK silencing was completely prevented by the protein transport inhibitor brefeldin-A, suggesting the involvement of CASK in trafficking processes. Finally, we showed that CASK expression is reduced in remodeled/dilated atrial biopsies without changes in localization. These results not only strengthen the concept of differentially regulated pools of Na\(_\text{v}1.5\) channels within the cardiomyocyte playing distinct roles in cardiac physiology, but also suggest that CASK could participate in maintaining low levels of Na\(_\text{v}1.5\) at the LM and consequently contribute to anisotropic conduction.
METHODS
An expended Methods section is available in the Online Data Supplement.

Cell preparations, Transfections and Adenoviral infections
Adult atrial or ventricular myocytes were obtained by enzymatic dissociation on a Langendorff column as previously described\(^1\). Adult rat atrial myocytes were infected with Ad-shscr, Ad-shCASK, Ad-GFP or Ad-CASK. HEK293 cells stably expressing Na\(_\text{v}1.5\) were transiently transfected with either shscr or shCASK and pIRES-GFP or pIRES-GFP-CASK.

Cardiac-specific CASK knockdown mouse
Mice were generated by Cre/loxP-mediated gene targeting through homologous recombination. The homozygous floxed CASK\(^{\text{tm1Sud}}\) mouse was bred with a cardiomyocyte-specific Cre-recombinase mouse, α myosin heavy chain (αMHC)-Cre.

Semi-quantitative real-time PCR
Details of specific primers designed to amplify cask, scn5a and housekeeping genes are described in the Online Data Supplement.

Protein extraction, Western Blot and Pull-down assays
These procedures were performed as previously reported\(^8,18\). See Online Data Supplement for other details.

Deconvolution microscopy, Evanescent field microscopy and Image analysis
3-D deconvolution epifluorescence and TIRF microscopy images were acquired as described previously\(^18\). Analysis was performed using ImageJ software (NIH). Details are given in the Online Data Supplement.

Electrophysiological measurements
Patch-clamp recordings were performed in the whole-cell configuration at room temperature. Detailed solutions and protocols are available in the Online Data Supplement.

Human samples
In accordance with approval of Institution Ethic Committee, biopsies of right atrial appendages were obtained from patients undergoing cardiac surgery. See Online Data Supplement.

Statistics
Data are represented as mean±SEM; \(*: P<0.05, **: P<0.01\) and \(***: P<0.001; ns: not significant.

RESULTS

The MAGUK CASK is expressed at the lateral membrane and excluded from the intercalated disc.
We first looked at the expression of CASK in adult myocardium by western blot. CASK was expressed both in rat atria and ventricle lysates, with a ~2 fold larger expression in atria. CASK was also expressed in myocyte- and fibroblast-enriched fractions (Figure 1A-B). Secondly, we examined the localization of CASK in rat atrial and ventricular myocardial cryosections using high resolution 3-dimensional (3-D) deconvolution microscopy. In ventricle, CASK was expressed along the LM stained with caveolin3 (Figure 1C, top panel) whereas no signal was detectable at the intercalated disc (ID) stained with N-cadherin (Figure 1C, middle). CASK also exhibited a striated pattern, facing the sarcomeric α-actinin corresponding to z-line (Figure 1C, bottom panel), suggesting either a T-tubular or a costameric localization. The distribution of
CASK regarding the different compartments of cardiomyocytes was similar in the atrial myocardium (Online Figure I).

**CASK is a new member of the dystrophin-glycoprotein complex at the lateral membrane of cardiomyocytes.**

In freshly isolated myocytes, CASK staining was apparent along the LM and exhibited the z-line superposition reported above. To investigate whether CASK was located at the T-tubule, co-immunofluorescence experiments were conducted with Ca$_{v}$1.2 or RyR2. However, little colocalization was observed in myocytes (Online Figure IIA). In addition, after detubulation by formamide treatment, the striated pattern was still observed in live ventricular myocytes stained with the voltage-sensitive dye Di-8-ANEPS (Online Figure IIB).

Next, the association of CASK with either vinculin or dystrophin costameric complexes was investigated in freshly isolated adult atrial myocytes (Figure 2A-B). CASK more closely associated with dystrophin (R: 0.68) than with vinculin (R: 0.31) (Figure 2A). In contrast with vinculin which is organized in rib-like structures at the sarcolemma, CASK showed a continuous layering of the sarcolemma, similar to dystrophin (Figure 2B). In addition, CASK and dystrophin displayed a regular interval alignment of ~2 µm, the interval between two z-lines, in the midsection of cardiomyocytes (Figure 2C). The association between CASK and dystrophin was further supported by co-immunoprecipitation experiments performed on whole heart lysates (Figure 2D). Finally, immunostainings performed on dystrophin-deficient mdx mouse ventricular cryosections showed a loss of CASK staining, suggesting that CASK expression at the LM of cardiomyocytes depends on dystrophin expression (Figure 2E). Note that the striated distribution of CASK was not observed in mouse myocardium, suggesting distinct costameric organization between species.

Altogether, these results indicate that CASK is poorly expressed at the T-tubule under normal conditions and is a new member of the dystrophin-glycoprotein complex.

**CASK directly interacts with Na$_{v}$1.5.**

Since Na$_{v}$1.5 associates with the dystrophin-glycoprotein complex at the LM$^{19}$, we explored the interaction of CASK with Na$_{v}$1.5. In freshly isolated atrial myocytes, CASK and Na$_{v}$1.5 exhibited both a sarcolemmal and striated expression and partially overlapped (R: 0.31) (Figure 3A-B). This partial overlap is likely due to high expression of Na$_{v}$1.5 channels at the ID where CASK is not present. Periodic intervals between two striations calculated using Fast Fourier Transform revealed a coherent distance of ~2 µm (Figure 3A). Of note, in this selected focal plane, the intercalated disc was not visible. The interaction between CASK and Na$_{v}$1.5 in the rat myocardium was supported by co-immunoprecipitation experiments (Figure 3C).

To investigate whether CASK could specifically interact with Na$_{v}$1.5, pull-down experiments were performed using the WT Na$_{v}$1.5 C terminus (Ct) or deleted for the PDZ binding motif corresponding to the 3 last SIV residues (ΔSIV, Figure 3D). Western blot experiments performed using anti-CASK and anti-pan syntrophin antibodies revealed that the Na$_{v}$1.5 WT Ct precipitated the two proteins from rat ventricle lysates. This interaction was dependent on the SIV motif of Na$_{v}$1.5 as interactions with CASK and syntrophin were respectively reduced by 94% and 61% with the truncated construct (Figure 3E). Finally, direct interaction between CASK and the Na$_{v}$1.5 Ct was investigated by performing pull-down experiments with the purified CASK protein (Figure 3F). At 10ng of purified CASK protein, the interaction was reduced by 21% but not abolished in ΔSIV.

These results support that CASK interacts directly with Na$_{v}$1.5 Ct, regardless of the presence of syntrophin, and that other residues than SIV are likely involved in this interaction.

**CASK regulates the sodium current in vitro.**

To assess the functional consequence of the interaction between CASK and Na$_{v}$1.5, $I_{Na}$ was recorded in adult atrial myocytes using whole-cell patch-clamp after modulating the expression of CASK. Representative images of adenoviral infection efficiency in cultured rat atrial myocytes are presented Online Figure IIIA. CASK was overexpressed using an adenoviral
construct containing the GFP reporter (Ad-CASK) and compared to GFP alone (Ad-GFP). CASK mRNA was increased by 120% and protein level by 200% in Ad-CASK after 3 days in vitro (D/I) (Online Figure IIB-D). Average current-voltage (I-V) plots from voltage clamp experiments showed a significant decrease in $h_{\text{Na}}$ density at different tested voltages in Ad-CASK (Figure 4A-C). CASK overexpression shifted the steady-state inactivation curve leftward by ~8 mV ($P<0.001$, Figure 4E) whereas no difference was found for activation properties between Ad-CASK- and Ad-GFP-infected cells (Figure 4D). Next, we used adenoviral transfer technology to knockdown CASK in adult rat atrial myocytes. Silencing experiments were performed using GFP adenoviral construct containing a shRNA for CASK (Ad-shCASK) and compared to a scramble shRNA (Ad-shscr). CASK mRNA was decreased by 60% and protein level by 40% in Ad-shCASK at 5 D/I (Online Figure IIIB-D). Voltage clamp experiments showed a significant increase in $h_{\text{Na}}$ at several tested voltages in Ad-shCASK (Figure 4B-F). No difference was found for activation properties between Ad-shCASK and Ad-shscr cells whereas steady-state inactivation was ~8 mV more positive in Ad-shCASK cells ($P<0.05$, Figures 4G-H). It is worth noting that the CASK-dependent shift in steady-state inactivation cannot explain the 2-fold change in $h_{\text{Na}}$ density. These experiments clearly demonstrate that CASK exerted a repressive function on $h_{\text{Na}}$.

The regulatory function of CASK on $h_{\text{Na}}$ is conserved in vitro from polarized cardiomyocytes to non-polarized HEK293 cells.

As CASK expression was restricted to the LM of cardiomyocytes, we investigated whether the regulatory function of $h_{\text{Na}}$ by CASK could be dependent on the loss of structural polarity and dedifferentiation under culture conditions.

We followed the distribution of CASK in cardiomyocytes in vitro in accordance with the distribution of the adherens junction protein N-cadherin. Immediately after dissociation, CASK was absent from the ID where N-cadherin was confined. At D/I1, N-cadherin started to be internalized and at D/I2, was randomly distributed in the cytoplasm. At the same stage, CASK was located at the cell membrane. After one week in culture (D/I7), cardiomyocytes had reestablished contacts (ID-like structures) in which N-cadherin was located and CASK excluded (Online Figure IV). Therefore, CASK localization appeared related to the architecture/polarity of cardiomyocytes.

Thus, to investigate whether the regulation of $h_{\text{Na}}$ by CASK could be polarity-dependent, we induced the formation of adherens junctions in vitro. Adult atrial myocytes infected with Ad-shscr or Ad-shCASK were seeded on Fc fragment plus N-cadherin (N-cadh) or Fc fragment alone, used as a control (Fc) (Online Figure VA). Atrial myocytes seeded on N-cadh showed both increased spreading and increased N-cadherin staining as shown by TIRF microscopy (Online Figure VA). Average I-V plots from voltage clamp experiments showed a significant increase in $h_{\text{Na}}$ density at several tested voltages in the two coating conditions (Fc and N-cadh) in Ad-shCASK infected myocytes (Online Figure VB). No difference was found between Ad-shCASK myocytes cultured on N-cadh or Fc for activation properties whereas the steady-state inactivation curve was significantly shifted rightward in Ad-shCASK myocytes in the two coating conditions (~12 and 10 mV respectively, $P<0.05$) (Online Figure VC-D).

Next, $h_{\text{Na}}$ was recorded in the non-polarized HEK293 cell line stably expressing cardiac Na\(_{\text{v}}\)1.5 α subunits (HEK293-Na\(_{\text{v}}\)1.5) (Online Figure VIA). We first overexpressed CASK using a GFP plasmid construct (CASK) and control HEK293-Na\(_{\text{v}}\)1.5 were transfected with GFP alone (GFP). CASK expression was 2-fold increased in CASK at 3D/I (Online Figure VIB-C). Average I-V plots from voltage clamp experiments showed a significant decrease in $h_{\text{Na}}$ density in CASK compared with control cells (Online Figure VID). CASK overexpression shifted the steady-state inactivation curve by ~6 mV ($P<0.05$, Online Figure VIE) whereas activation properties were unchanged (Online Figure VIE-F). We next used CASK sh-RNA plasmid with the RFP reporter (shCASK) to transfect HEK293-Na\(_{\text{v}}\)1.5; scramble shRNA with RFP was used as control (shscr). CASK protein level was decreased by 45% in shCASK at 5 D/I (Online Figure VIB-C). Voltage clamp experiments showed a significant increase in $h_{\text{Na}}$ density at several tested voltages in shCASK-transfected cells (Online Figure VIG). Steady-state
inactivation was ~6 mV more positive in shCASK cells (P<0.01) whereas no difference was found for activation properties between groups (Online Figure VIH-I).

These results confirmed that CASK is excluded from ID structures and established that the negative regulatory function of CASK is a conserved mechanism.

The regulatory function of CASK is conserved in myocytes from CASK knockout mouse.

To assess the functional regulation of sodium channels by CASK in vivo, $I_{Na}$ was recorded in freshly isolated ventricular myocytes from αMHC-Cre/CASK and αMHC-Cre/WT mice. The homozygous floxed CASK$^{tm1Sud}$ mouse was bred with a α myosin heavy chain (αMHC)-Cre mouse to target cardiomyocytes. Recombination with αMHC-Cre leads to 68% CASK knockdown (KD) in cardiomyocytes (p<0.01, N=3, Figure 5A). The incomplete extinction of CASK is likely due to contamination by non-myocyte cells. Average I-V plots from voltage clamp experiments performed on HEK293 infected cells revealed that $I_{Na}$ density at several tested voltages in CASK KD compared with WT Cre myocytes (Figure 5B-C). No significant differences were found for activation properties and steady-state inactivation between CASK KD and WT Cre mouse myocytes (Figure 5D-E).

The results obtained in CASK KD ventricular myocytes together with the results obtained in HEK293-Na$_{v}$1.5 and cultured atrial myocytes support that CASK-induced effect is not dependent on the experimental model used nor on atrial versus ventricular myocytes.

CASK affects trafficking of Na$_{v}$1.5.

Since $I_{Na}$ was regulated by CASK expression level, we dissected out the mechanisms of Na$_{v}$1.5 regulation.

RT-qPCR experiments were performed to investigate whether CASK influenced the expression level of scn5a. However, the copy number of scn5a was not different between controls and CASK-overexpressing or CASK-silenced myocytes (Figure 6A). Western blots performed form lysates of Ad-shscr and Ad-shCASK infected atrial myocytes revealed that Na$_{v}$1.5 protein expression was not modified by CASK silencing. Interestingly, CASK silencing impacted syntrophin level, reducing its expression by 34% (p<0.001), whereas dystrophin levels remained unchanged (Online Figure VII). Biotinylation experiments were performed to assess Na$_{v}$1.5 surface expression. In Ad-shCASK myocytes, Na$_{v}$1.5 expression was reduced by ~20% in the total fraction whereas increased by ~45% in the membrane fraction (P<0.05, Figure 6B). TIRFm experiments also demonstrated a ~20% increase in surface staining of Na$_{v}$1.5 in Ad-shCASK myocytes (P<0.001, Figure 6C). These results showed that the increase in $h_{Na}$ upon CASK silencing was not transcriptional nor translational and rather due to increased surface expression of Na$_{v}$1.5. Therefore, a likely explanation was that CASK regulates anterograde trafficking and/or stabilization at the sarcolemma.

As the canonical early step in ion channel trafficking is the transport from the endoplasmic reticulum (ER) to the Golgi apparatus, the hypothesis of an increased forward trafficking was tested in silencing conditions. 12h post-infection with Ad-shscr or Ad-shCASK, cardiomyocytes were treated for 48h with brefeldin-A (BFA) prior to electrophysiological recordings. Voltage-clamp experiments showed that $h_{Na}$ density was not increased in Ad-shCASK-infected cells after BFA treatment (Figure 6D). TIRFm experiments also showed a reduced Na$_{v}$1.5 surface staining in Ad-shCASK myocytes treated with BFA (Figure 6E). In addition, biotinylation experiments performed on HEK293-Na$_{v}$1.5 cells showed that the increase in Na$_{v}$1.5 surface expression was reduced after BFA treatment in shCASK cells (Figure 6F).

Therefore, these results indicate that alterations in trafficking processes are involved in the effect of CASK in the regulation of $h_{Na}$.

CASK silencing modulates the expression of Na$_{v}$1.5 channels at the lateral membrane.

To understand further the mechanisms of Na$_{v}$1.5 regulation by CASK, we investigated whether CASK silencing affected a specific Na$_{v}$1.5 channel population.
Ad-shscr or Ad-shCASK infected atrial myocytes were cultured at half confluence, a situation that allows formation of cell contacts (ID-like structures) between some myocytes as well as the preservation of free membranes (LM-like structures) (Figure 7A). Immunostainings of Na\textsubscript{v}1.5 channels were performed and quantified by drawing lines in contact zones versus free membranes. As shown Figure 7B, the Na\textsubscript{v}1.5 signal was increased by ~21% at LM (p<0.01) and by ~10% at ID (not significant) in CASK-silenced myocytes (Figure 7B). These results support that the LM membrane pool of Na\textsubscript{v}1.5 channels is more susceptible to CASK modulation. In addition, it supports the concept that different Na\textsubscript{v}1.5 pools co-exist in cardiomyocytes.

**CASK expression is downregulated in remodeled atria whereas its localization is unchanged.**

Given the specific targeting of CASK to the costamere, we examined whether the expression and localization of the protein could be altered during conditions characterized by the remodeling of myocardial structure and of myocyte architecture such as dilated atria\textsuperscript{18,20,21}.

In control human atrial tissue samples, CASK was expressed at the LM and excluded from ID as in rat (Figure 8A). In patients with dilated atria, CASK remained localized at the costamere whereas its expression level was reduced as evidenced by fainter fluorescence intensity (p<0.001. Figure 8B) and a by ~42% decrease in total protein expression (p<0.01, Figure 8C). Chronically hemodynamic atrial overload associated with the development of ischemic heart failure in rat is also characterized by profound ultrastructural alterations of atrial myocytes\textsuperscript{18,20}. In this model too, CASK protein expression was decreased whereas its localization in membrane subdomains remained unchanged (Online Figure VIII). These results indicate that CASK expression in downregulated during atrial remodeling.

**DISCUSSION**

This study is the first characterization of CASK in cardiomyocytes. We found that CASK is the sole cardiac MAGUK protein identified so far excluded from the ID and strictly located at LM, where it associated with dystrophin. We showed that CASK directly interacts with Na\textsubscript{v}1.5 C-terminus and downregulates the sodium current. CASK silencing decreases syntrophin protein levels without impacting Na\textsubscript{v}1.5 or dystrophin expression levels. We demonstrated that CASK modulates the early trafficking of Na\textsubscript{v}1.5 and prevents its functional expression at the cell surface, and more specifically at the lateral membrane. Finally, we showed that CASK expression is reduced during atrial remodeling but its localization unchanged.

**Unique localization of CASK in cardiomyocytes.**

The two already known cardiac MAGUK proteins, SAP97 and ZO-1, are both preferentially expressed at the ID, a membrane domain specialized in the rapid propagation of action potentials (AP) along cardiac fibers. ID, located at the ends of cardiomyocytes, are the sites of intense electrical activity and concentrate numbers of ion channels, notably the main cardiac sodium channel, Na\textsubscript{v}1.5. It has been proposed that this organization facilitates longitudinal propagation of the AP over transverse propagation and determines conduction velocity (CV)\textsuperscript{22}.

Na\textsubscript{v}1.5 channels located at the ID are associated with different partners such as connexin-43\textsuperscript{2}, plakophilin-2\textsuperscript{3,4}, ankyrin-G\textsuperscript{5,6}, and SAP-97\textsuperscript{7,8}. All of these partners participate in anchoring/stabilization of Na\textsubscript{v}1.5 at the ID. In accordance, the sodium current recorded by macro-patch in the midsection of cardiomyocytes (LM) is of smaller amplitude than the current recorded at the ID\textsuperscript{23-25}. At the LM, Na\textsubscript{v}1.5 has been shown to interact with the dystrophin/syntrophin complex\textsuperscript{19}. In the dystrophin-deficient mdx mouse model of Duchenne muscular dystrophy, the LM pool of Na\textsubscript{v}1.5 is strongly reduced and h\textsubscript{Na} is decreased by ~30%\textsuperscript{8,19}. In agreement, transverse CV is more reduced than longitudinal CV in ΔSIV mouse hearts\textsuperscript{25}. From these observations, a scheme can be drawn concerning the relative contribution of the populations of Na\textsubscript{v}1.5 in the propagation of the AP: the ID pool having a higher weight.
than the LM pool. Our results indicate that CASK could participate in the maintenance of low level of functional Na\textsubscript{v}1.5 at the LM.

**CASK, a new member of the dystrophin-glycoprotein/Na\textsubscript{v}1.5 macromolecular complex.** Scanning ion conductance microscopy (SICm) identified three topographic entities in the LM: T-tubules, crests and z-grooves, the latter corresponding to T-tubule openings\textsuperscript{26}. Like T-tubules, crests show a periodicity of ~2 μm\textsuperscript{27}. Here, we focused on the LM distribution of CASK into microdomains using high resolution 3-D deconvolution microscopy. We showed that CASK was in closer association with dystrophin than with vinculin, two costameric proteins. In addition, we showed that CASK was able to precipitate dystrophin and that CASK staining at LM was distinct in mdx cardiomyocytes, suggesting that dystrophin is necessary for proper localization of CASK. However, in contrast to dystrophin which also extends along T-tubules in the rat myocardium, CASK was not found deep in the T-tubule since it did not colocalize with calcium channels or ryanodine receptors and its expression pattern was not affected by detubulation.

Interestingly, we showed that CASK silencing reduced syntrophin levels, whereas dystrophin and Na\textsubscript{v}1.5 levels were unchanged. In addition, we showed that CASK directly interacts with the Na\textsubscript{v}1.5 channel C-terminus using myocyte enriched fraction from rat heart lysates. Moreover, Na\textsubscript{v}1.5 C-terminus also interacted with purified CASK protein, suggesting that Na\textsubscript{v}1.5 and CASK interaction is not dependent on the presence of syntrophin. Altogether, these results suggest that CASK is downstream dystrophin and upstream syntrophin and that syntrophin and CASK could compete for Na\textsubscript{v}1.5 channel binding, likely at early stages of trafficking.

Super-resolution scanning patch-clamp recordings showed that Na\textsubscript{v}1.5 channels do not distribute homogenously along the LM but instead form clusters confined into functional microdomains, with the largest aggregated at crest regions\textsuperscript{27}. Here, we showed that CASK, Na\textsubscript{v}1.5 and dystrophin all displayed a periodicity of 2 μm and that CASK was associated with Na\textsubscript{v}1.5. In light of this distribution and poor expression in T-tubules, one could speculate that the macromolecular complex formed by Na\textsubscript{v}1.5, CASK and dystrophin corresponds to crest structures identified by SICm. The differential distribution of Na\textsubscript{v}1.5 in microdomains of the LM suggests distinct roles for crests and T-tubules in electrical and contractile activities of cardiomyocytes. For instance, Na\textsubscript{v}1.5 located at the crest could play a preferential role in the propagation of the action potential along the LM whereas those located in T-tubules could be involved in EC coupling. In this line, the specific localization of CASK at LM and its exclusion from T-tubules suggests a role for CASK in the regulation of the surface pool/crest population of sodium channels.

**Mechanisms of regulation of \textit{I}_{\text{Na}}\textit{v} by CASK.** MAGUKs are multidomain scaffolding proteins known to be involved in trafficking, targeting, and signaling of ion channels and receptors. In neurons, differential sorting of glutamate receptor subtypes has been shown to start in the endoplasmic reticulum (ER) and to depend on SAP97 and CASK. While AMPARs are trafficked to the plasma membrane via the classical secretory pathway, NMDARs are diverted towards a specialized ER sub-compartment. This ER sub-compartment is composed of NMDAR subunits, CASK and SAP97. While CASK does not directly bind to NMDAR, it prevents the SAP97-dependent ER retention of NMDAR\textsuperscript{28}. When bound to CASK, SAP97 colocalizes with NMDAR while, when unbound, SAP97 preferentially associates with AMPAR\textsuperscript{29}. These studies suggest that CASK regulates SAP97 association with glutamate receptor subtypes and subsequent sorting and trafficking to correct location. In cardiomyocytes, Shy et al. showed that the last 3 residues of Na\textsubscript{v}1.5 in C-terminal, the SIV motif, are essential for the localization of Na\textsubscript{v}1.5 at the LM, but not required for its expression at the ID and t-tubules\textsuperscript{25}. The SIV motif interacts with syntrophin at the LM and with SAP97 at the ID, thereby defining distinct pools of Na\textsubscript{v}1.5 multiprotein complexes. However, the mechanisms regulating the differential sorting of Na\textsubscript{v}1.5 to specific membrane subdomains have not been elucidated.
In this context, the present study provides new insights in processes regulating the sorting of NaV1.5. Our results revealed that CASK exerts a repressive effect on the functional expression of NaV1.5. In vitro silencing or in vivo knockdown of CASK increased \( I_{\text{Na}} \). In addition, this negative regulatory function was conserved for both atrial and ventricular myocytes. We showed that the current increase observed following CASK-silencing was due to increased surface expression of NaV1.5, and more specifically, at the LM. Treatment with the inhibitor of forward transport between ER and Golgi apparatus, BFA, prevented the effect. This result shows that CASK impedes NaV1.5 trafficking. Therefore, one could hypothesize that NaV1.5 sorting could be determined during anterograde processing steps of trafficking. Despite a common biosynthetic pathway, the early association of the channel with \( \beta \) auxiliary subunits and/or with other partners during biosynthesis could determine its sorting and final targeting to specific subdomains. Our results support that CASK plays a role in maintaining low level of NaV1.5 at the LM by repressing a yet unknown identified step of channel trafficking. In this regard, CASK is unique among MAGUK proteins investigated so far that usually favors anchoring/stabilization of ion channels at the sarcolemma.

**CASK expression is reduced during atrial remodeling.**

Costameres encircle myocytes perpendicularly to their longitudinal axis in alignment with z-lines, making the bridge between extracellular matrix, sarcolemma and intracellular contractile sarcomeres. They reinforce the sarcolemma during cardiac workload and transmit contractile forces exerted by myocytes or extracellular matrix in a bidirectional manner\(^3\).

Both in human and rat diseased atria characterized by extensive structural alterations of atrial myocytes\(^2\), CASK expression levels was reduced whereas its LM localization was not modified. Whether this downregulation of CASK is associated with the redistribution of NaV1.5 subpopulations in diseased myocardium needs to be carefully examined.

In summary, this study constitutes the first description of an unconventional MAGUK protein both in terms of localization and function in the heart. CASK acts as a repressor of the population of NaV1.5 dedicated to the LM by preventing early trafficking. These results represent a substantial step forward in the concept of differentially regulated pools of NaV1.5 within the cardiomyocyte having distinct roles in cardiac physiology. Notably, CASK could participate in maintaining low level of NaV1.5 at the lateral membrane and consequently, contribute to the anisotropic conduction.

**ACKNOWLEDGMENTS**

We thank Dr. H. Boycott for careful reading of the manuscript and helpful comments. We acknowledge the contribution of S. Vermij in acquiring data and preparing material for the Figs. 3 and 5. We thank M. Essers (Dpt. of Clinical Research, University of Bern, Switzerland) for kindly providing the mdx mouse heart samples. We thank Dr. N. Mougenot of PECMV Platform, Pitié-Salpêtrière Hospital, France, for helpful assistance with the animal model.

**SOURCE OF FUNDING**

This work was supported by Fondation Leducq “Structural Alterations in the Myocardium and the Substrate for Cardiac Fibrillation” (EB and SNH), the European Union (EUTRAF-261057; EB and SNH), and the AFM-Telethon with the reference 17758 (EB), and the Swiss National Science Foundation (grant #310030_165741, HA).

NOVELTY AND SIGNIFICANCE

What Is Known?

- Cardiac sodium channels are located in distinct membrane domains of the cardiac myocyte and interact with several partners, defining different populations of sodium channels which could play different roles in cardiac electrophysiology.

- At the intercalated disc, a high concentration of sodium channels are found in interaction with several anchoring partners where they contribute to the fast and longitudinal propagation of the action potential.

- While recent studies have identified another subpopulation of sodium channels at the lateral membrane which underlies a sodium current of small amplitude, the partners and mechanisms regulating this subpopulation are still largely unknown.

What New Information Does This Article Contribute?

- In atrial and ventricular myocardium, we identified a new MAGUK protein, CASK, which is restricted to the lateral membrane of cardiomyocytes and interacts with both the dystrophin-glycoprotein complex and sodium channels, defining a new multi-molecular complex in this specific membrane domain.

- CASK negatively regulates the sodium current both in vitro and in vivo and reduces the surface expression of sodium channel at the lateral membrane by impeding channel trafficking.

- CASK appears as a crucial determinant of the organization of the subpopulation of sodium channel of the lateral membrane; its reduced expression in diseased myocardium might contribute to the alteration of the normal anisotropic propagation of the electrical influx.

Cardiomyocytes are highly organized cells characterized by specific plasma membrane domains specialized in mechanical and electrical functions. These domains are constituted by macromolecular complexes containing several ion channels and partners, particularly well described for the intercalated disc. Here, we describe a new macromolecular complex at the lateral membrane of cardiomyocytes which organizes a subpopulation of sodium channels. We found that the MAGUK protein CASK is an unconventional partner of Na\textsubscript{v}1.5 channels in cardiomyocytes. CASK is specifically distributed in costameric structures of the lateral membrane in association with dystrophin. We show that CASK directly interacts with Na\textsubscript{v}1.5 and negatively regulates the corresponding current both in vitro and in vivo and impedes Na\textsubscript{v}1.5 trafficking to the plasma membrane. Finally, we show that CASK expression is reduced in remodeled/dilated atrial biopsies without changes in localization. These results not only strengthen the concept of differentially regulated pools of Na\textsubscript{v}1.5 channels within the cardiomyocyte but also suggest that CASK could participate in maintaining low levels of active Na\textsubscript{v}1.5 at the lateral membrane. Given the role of Na\textsubscript{v}1.5 in the fast activation and propagation of the action potential, the repressive effect of CASK on Na\textsubscript{v}1.5 could contribute to the anisotropic conduction of the depolarization wave.
