Abstract:

The relationship between Eurasian snow cover extent (SCE) and Northern Hemisphere atmospheric circulation is studied in reanalysis during 1979-2014 and in CMIP5 preindustrial control runs. In observations, dipolar SCE anomalies in November, with negative anomalies over eastern Europe and positive anomalies over eastern Siberia, are followed by a negative phase of the Arctic Oscillation (AO) one and two months later. In models, this effect is largely underestimated, but four models simulate such relationship. In observations and these models, the SCE influence is primarily due to the eastern Siberian pole, which is itself driven by the Scandinavian pattern (SCA), with a large anticyclonic anomaly over the Urals. The SCA pattern is also responsible for a link between Eurasian SCE anomalies and sea ice concentration (SIC) anomalies in the Barents-Kara Sea.

Increasing SCE over Siberia leads to a local cooling of the lower troposphere, and is associated with warm conditions over the eastern Arctic. This is followed by a polar vortex weakening in December and January, which has an AO-like signature. In observations, the association between November SCE and the winter AO is amplified by SIC anomalies in the Barents-Kara Sea, where large diabatic heating of the lower troposphere occurs, but results suggest that the SCE is the main driver of the AO. Conversely, the sea ice anomalies have little influence in most models, which is consistent with the different SCA variability, the colder mean state, and the underestimation of troposphere-stratosphere coupling simulated in these models.

45

## 46 **1. Introduction**

47 The role of Arctic conditions in the mid-latitude winter climate is under debate,  
48 especially for the North Atlantic sector (Overland et al. 2015). In this region, the  
49 atmosphere has a dominant short-timescale chaotic intrinsic variability and is mainly  
50 unpredictable. However, several studies suggest that the variability of Arctic sea ice  
51 extent (Yamamoto et al. 2006; Francis et al. 2009; Honda et al 2009; Wu and Zhang  
52 2010; Frankignoul et al. 2014; Garcia-Serrano et al. 2015, Koenigk et al. 2016, King et al.  
53 2016) and Eurasian snow cover extent (SCE, e.g. Cohen and Entekhabi 1999, Cohen et al.  
54 2007, Cohen and Jones 2011) have some influence onto the atmosphere during winter.  
55 Such influence may account for an improvement in skill of long-range prediction due to  
56 continental snow (Jeong et al., 2013, Orsolini et al., 2013) and sea ice (Scaife et al. 2014)  
57 initialization and improved physics (Riddle et al. 2013) in current forecast systems.

58 Continental snow cover affects the atmosphere via changes in surface albedo  
59 (Cohen 1994). A larger snow cover increases the surface albedo and reflects shortwave  
60 radiation away from the surface (Gong et al. 2004, Jeong et al., 2013). A snowpack also  
61 insulates the atmosphere from the soil surface. In winter at high latitude, these two  
62 effects explain that snow enhances the diabatic cooling at the surface and in the  
63 atmospheric boundary layer (Fletcher et al. 2007; Dutra et al. 2011), which locally  
64 increases the sea level pressure (SLP). A larger SCE over Eurasia has been reported to  
65 intensify and expand the Siberian high (Jeong et al., 2011; Orsolini et al., 2013). This  
66 modifies the land/sea contrast and the stationary wave pattern, and may lead to  
67 enhanced upward planetary wave propagation, thus weakening and warming the polar  
68 vortex in the stratosphere (Saito et al., 2001, Cohen et al. 2007, Orsolini et al., 2016). A  
69 weak polar vortex can persist for several weeks and influence the underlying

70 troposphere by downward propagation of circulation anomalies. The influence of the  
71 Eurasian snow cover has received most attention in autumn, as it shows a statistically  
72 significant relation with the following winter Arctic Oscillation (AO) and North Atlantic  
73 Oscillation (NAO), from December to March (Cohen et al., 2007; Déry and Brown, 2007;  
74 Allen and Zender, 2010; Cohen et al., 2012).

75         Sea ice concentration (SIC) changes may also influence the atmosphere. The most  
76 reported influence concerns SIC in the Barents-Kara Sea, where SIC in autumn has a  
77 statistically significant influence on the following winter NAO (Petoukov and Semenov,  
78 2010; Kim et al., 2014; Garcia-Serrano et al., 2015; King et al., 2016). Sea ice insulates  
79 the ocean from the atmosphere, so that a sea ice loss increases the heat flux from the  
80 ocean to the atmosphere. The resulting diabatic heating is large, but localized near the  
81 sea ice edge (e.g. Magnusdottir et al. 2004; Deser et al. 2004, 2007). This leads to  
82 changes in the tropospheric eddies and the planetary wave pattern, which may alter the  
83 polar vortex (e.g. Nakamura et al. 2015, 2016). The modified polar vortex may then  
84 influence the troposphere by downward propagation in the following weeks or months,  
85 with important impact during periods of polar vortex breakdown, such as in February  
86 (Jaiser et al. 2016).

87         The influence of SIC thus shares a large similarity with that of the Eurasia SCE  
88 during fall (October and November), as both may involve a stratospheric pathway.  
89 Furthermore, continental SCE and Arctic SIC are linked, as a reduced Arctic sea-ice  
90 extent leads to a moistening of the atmospheric boundary layer, which increases the  
91 moisture flux into eastern Siberia, increasing snowfall, as suggested by Cohen et al.  
92 (2014a) and found by Wegmann et al. (2015) using a Lagrangian analysis. The sea ice  
93 and snow cover are also connected by the influence of Ural Blocking, which has been  
94 reported to cause warm Arctic–cold Eurasia anomalies in winter (Luo et al., 2016). The

95 two surface influences are, therefore, connected, and their interaction might amplify the  
96 atmospheric response found by separately considering snow cover and sea ice (Cohen et  
97 al. 2014a). However, only a few studies have investigated the links between the SCE and  
98 sea ice. The relative effect on the atmosphere of the Arctic sea ice and Eurasian snow  
99 cover is largely unknown. In addition, the influence of tropical SST variability needs to  
100 be clarified, as the tropical teleconnections may both influence the snow cover over  
101 Eurasia and modify the atmospheric circulation (Fasullo, 2004), leading to a possible  
102 confusion between cause and effect.

103         As the observational record is mostly limited to the recent decades, climate  
104 models can be used to investigate the impact of SIC and SCE variability with a much  
105 larger sampling, even if the stratospheric polar vortex is too stable in models, which may  
106 inhibit the troposphere-stratosphere coupling (Furtado et al., 2015). The aim of this  
107 study is to investigate the influence of autumnal Eurasian snow cover variability in  
108 observations and climate models, and the links with that of the sea ice cover. We find  
109 that snow cover anomalies in November have a dominant influence on the atmospheric  
110 circulation in observations and several models. The SCE anomalies are found to be  
111 associated with SIC anomalies over the Barents-Kara Sea, as both are modulated by the  
112 Scandinavian pattern, which is the dominant mode of atmospheric variability in  
113 November.

114         The next section describes the methodology. The analysis of the snow cover and  
115 its links with the atmosphere is discussed in Section 3. The processes linking the snow  
116 cover to the atmosphere are investigated in Section 4. Finally, the last section contains  
117 the discussion and conclusions.

118

119

## 120 **2. Data and methods**

### 121 *a. Observations*

122 Monthly sea ice cover is downloaded from the NOAA/National Snow and Ice Data  
123 Center (Comiso, 2012). Weekly Northern Hemisphere continental snow cover is  
124 retrieved from the NOAA/Rutgers University Global Snow Laboratory, and aggregated  
125 into monthly data. Both products are based on passive microwave measurements  
126 (SSM/I) and extend from 1979 to 2014. The sea-level pressure (SLP), geopotential  
127 height, air temperature, and heat flux (accumulated from 24h forecasts) are from the  
128 ERA-Interim reanalysis (Dee et al., 2011).

129 A quadratic trend is removed from all variable before the analysis to remove the  
130 effect of the global warming. This also removes the multi-decadal variability and lower  
131 frequencies, and the large Arctic sea ice decrease from 2005 onward (e.g. Close et al.  
132 2015).

133

### 134 *b. Models*

135 Monthly SLP, snow cover, geopotential, SIC, SST and heat fluxes anomalies are  
136 downloaded from the CMIP5 archive for 12 coupled ocean atmosphere models (Table 1)  
137 using the preindustrial multi-centennial control simulations with constant external  
138 forcing. All model fields are interpolated onto a common  $2.5^{\circ} \times 2.5^{\circ}$  horizontal grid. A  
139 quadratic trend was removed from all outputs to remove the possible influence of model  
140 drift.

141

### 142 *c. Maximum covariance analysis*

143 Maximum covariance analysis (MCA) is used to estimate the main modes of area-  
144 weighted covariability between the atmosphere and the underlying snow cover. We use

145 snow cover anomalies over northern Eurasia ( $40^{\circ}\text{N}$ - $65^{\circ}\text{N}$ ;  $0^{\circ}\text{E}$ - $180^{\circ}\text{E}$ ). The SLP  
146 anomalies in the Northern Hemisphere ( $20^{\circ}\text{N}$ - $90^{\circ}\text{N}$ ) are chosen to represent the  
147 tropospheric circulation. The MCA decomposes the covariance matrix of the two fields  
148 using singular value decomposition (Bretherton et al., 1992). Each mode of covariability  
149 is characterized by two times series and associated spatial patterns. Here, the MCA time  
150 series are standardized (divided by their standard deviation). The spatial patterns are  
151 illustrated by the homogeneous covariance map for the field that leads (regression on  
152 the same field time series) and the heterogeneous covariance map for the field that lags  
153 (regression on the MCA time series of the other field), which preserves orthogonality  
154 (Czaja and Frankignoul, 2002). The MCA modes are characterized by their normalized  
155 squared covariance (NSC, i. e. the squared singular value divided by the variance of both  
156 fields), the correlation (R) between the MCA time series, and the squared covariance  
157 fraction (SCF, i. e. the ratio of covariance explained). In order to evaluate the robustness  
158 of the MCA modes, we repeated the MCAs using 100 random permutations of three-  
159 years blocks for the SLP field. The number of NSC and R that exceed the observed values  
160 gives the levels of significance for NSC and R.

161         The mode of covariability between the snow cover and the atmosphere are  
162 expected to reflect the influence of atmospheric perturbations on the SCE when the two  
163 fields are in phase or, because of snow cover persistence, when the atmosphere leads.  
164 When the snow cover leads the atmosphere by one month or more, a significant MCA  
165 mode could indicate an influence of the snow cover (or concomitant boundary forcing)  
166 on the atmosphere, as the extratropical atmosphere has an intrinsic persistence of at  
167 most 10 days (Vautard, 1990). However, the El Niño Southern Oscillation (ENSO) has  
168 persistent remote teleconnections that may give rise to persistent MCA modes not solely  
169 linked to local boundary forcing. Hence, we (largely) remove these teleconnections from

170 both snow and atmospheric data by multivariate regression when (and only when) the  
171 snow cover field leads the atmosphere, assuming that they lag the tropical Pacific SST by  
172 two months in the atmosphere, while they vary with lag for the snow in order to get  
173 unbiased estimates (see Frankignoul et al., 2011). The tropical SST variability is  
174 represented by the first three empirical orthogonal functions (EOFs) of the monthly  
175 tropical Indo-Pacific SST. The regressions are performed separately for each season, to  
176 account for the seasonal changes of the ENSO teleconnection, and separately for positive  
177 and negative values of the Principal Components (PCs), to account for the asymmetry  
178 (see supplemental material text for details). We verified that similar MCA results are  
179 obtained by assuming a one-month lag for the ENSO teleconnections, or even without  
180 removing the ENSO signal (see Table S1).

181

#### 182 *d. Rotated empirical orthogonal function*

183 The main patterns of Northern Hemisphere (20°N - 90°N) SLP variability are  
184 given by rotated empirical orthogonal function (REOF) analysis, using the first 15 EOFs  
185 in the rotation, which accounts for 95% of the variance. To preserve orthogonality of the  
186 PCs, we scaled the EOFs by the square root of its eigenvalue before performing the  
187 varimax rotation (Kaiser 1958). The rotated PCs are standardized, and the REOF  
188 patterns are given by regression on these time series.

189

#### 190 *e. Regression analysis*

191 We used both univariate and multivariate least squares regression. We remove  
192 the tropical teleconnections from all data before the regression analysis, following the  
193 same methodology as the MCA (see section 2.c). The level of statistical significance is  
194 tested with 100 permutations of the atmospheric fields in 3-yr blocks to take serial

195 autocorrelation into account. The number regression slopes that exceeds the observed  
196 value in the permuted time series provides the p-value.

197

### 198 **3. The links between Eurasian snow cover and the atmosphere**

#### 199 *a. Detection of the snow cover influence*

200 The normalized squared covariance (NSC) of the first MCA mode provides an  
201 estimate of the dominant covariability between the SCE and SLP anomalies. It is shown  
202 as a function of lag and season for the observations in Fig. 1. The largest NSC are mostly  
203 obtained when the atmosphere is in phase with the SCE or leads it by one month  
204 (negative lag), reflecting that the atmosphere controls the formation of snow cover  
205 anomalies. The largest covariability occurs for SLP in March at lag 0 and for SLP in  
206 February when it leads by one month. This is consistent with the occurrence of the  
207 largest interannual snow anomalies in March, and the largest atmospheric variability in  
208 February.

209 At positive lag, the snow cover leads the atmosphere, which may reflect the SCE  
210 forcing of atmospheric anomalies. The most significant links are found between  
211 November snow cover and SLP in December (lag 1) and January (lag 2), as well as  
212 between February snow cover and SLP in March (lag 1), as the NSC and R are both  
213 significant at the 5% level (Fig. 1). The covariability is weaker when October SCE leads  
214 the atmosphere, whether by 1, 2 or 3 months (p-values are 10%, 28%, 40% for NSC and  
215 13%, 38%, 20% for R). Our results thus contrast with the commonly argued impact of  
216 October Eurasian snow cover on winter SLP (Saito and Cohen, 2003), as further  
217 discussed in Appendix. A significant covariance (p-value<10%) is also found for SLP in  
218 August and September, when the SCE leads by one month.

219           The influence of November SCE onto the atmosphere in December and January is  
220 the main focus of this paper, and it is discussed below. The late winter snow influence  
221 found in March has been reported in several studies (Barnett et al., 1989; Saito and  
222 Cohen, 2003; Zhang et al., 2004; Peings and Douville, 2010; Peings et al. 2011); it is not  
223 investigated here, as the processes are different from the fall influence studied here.  
224 Similarly, the covariability in late summer is not discussed here; it shows a reduction of  
225 snow cover in south-western Norway preceding anticyclonic conditions over the North  
226 Atlantic (not shown), and might be due to concomitant North Atlantic SST forcing  
227 (Gastineau and Frankignoul, 2015).

228           The same analysis has been performed with the CMIP5 models, and a significant  
229 covariability between SCE and SLP anomalies is found in several cases. The results are  
230 summarized in Fig. 2, which shows the level of statistical significance of the NSC and R  
231 for the first MCA mode (left panel). The similarity with the observational data is given  
232 by the spatial pattern correlation of the homogeneous SCE and heterogeneous SLP  
233 covariance maps between each model and the observation (right panel). When using  
234 November SCE anomalies and December SLP (black symbols in Fig. 2), there are four  
235 models out of 12 (CanESM2, MPI-ESM-LR, GISS-E-R and CESM1) suggesting an impact of  
236 the November SCE anomalies that is reasonably similar to that observed (spatial  
237 correlation between 0.2 and 0.9). These four models show a first MCA mode that is 10%  
238 significant for NSC and R, except for MPI-ESM-LR, which is only 12% significant for R.  
239 Among these four models, only CESM1 is a low-top model, while the others are high top  
240 models with lid height above 45km (Seviour et al., 2016).

241           The SCE influence seems to be less persistent in models, as the first MCA mode  
242 with November SCE is only significant at lag 2 (SLP in January) in CESM1 (red symbols  
243 in Fig. 2). When using October SCE and November SLP (blue symbols in Fig. 2), there are

244 only two models out of 12 suggesting an impact of the October snow cover anomalies  
245 (CSIRO-Mk3-6 and CCSM4). When using October SCE and December (January) SLP, only  
246 one model, FGOALS-g2 (IPSL-CM5A-LR), provides a potential impact. We conclude that  
247 consistent with observations, more CMIP5 models suggest an impact of November SCE  
248 than October SCE. Next, we will discuss the spatial patterns corresponding to these  
249 modes of covariability.

250

251 *b. Spatial pattern of the November snow cover influence*

252 The covariance maps for November SCE and December SLP are shown in Fig. 3. In  
253 observations, the first MCA mode shows dipolar snow cover anomalies (Fig. 3a, colors),  
254 with a pole over eastern Europe and an opposite polarity over south-eastern Siberia,  
255 Northern Mongolia, and Northern China. Both poles are located at the margin of the  
256 snow-covered surface in November (see Fig. S1). This SCE dipole precedes SLP  
257 anomalies (black contours) broadly projecting on a negative phase of the AO, with a  
258 large signature over the North Atlantic. The covariance maps at lag 2 (Fig. 3b, November  
259 SCE / January SLP) are almost identical, but the SLP anomalies are weaker, especially  
260 over Western Europe. Note that the covariance maps at lag 3 (November SCE / February  
261 SLP) are also similar, although the significance level for NSC and R are 1% and 27%,  
262 respectively.

263 The MCA patterns in the four CMIP5 models (CanESM2, MPI-ESM-LR, GISS-E-R,  
264 CESM1) identified previously are broadly similar to the observed ones (Fig. 3c-f), with a  
265 positive snow cover anomaly in southern Siberia and a negative one over eastern  
266 Europe preceding a negative AO-like pattern by one month. However, the amplitudes  
267 are smaller than in observations (note the different color and contour interval in Fig. 3).  
268 Furthermore, the snow cover anomalies are slightly shifted, as the November SCE

269 climatology shows less snow over Eurasia, especially over Europe (Fig. S1). In the  
270 following, we only consider this subset of four models, as illustrated by the averaged  
271 covariance map (Fig. 3g).

272 To take into account the different sampling in models ( $\geq 500$  yr) and  
273 observations (36 yr), we performed similar MCA analysis on separate 36-yr segments  
274 from each of the four model simulations. These 36-yr segments are selected using a shift  
275 of 6 years between two consecutive ones, so that for instance a 1000-yr run results in  
276 160 36-yr segments. The mean NSC and R for the first MCA mode in these segments are  
277 larger than the ones computed from the entire run (compare Fig. 3h and values on top of  
278 Fig. 3c-f), but still smaller than in observations, with the 95% percentile of their  
279 distributions lower than the observed value. Therefore, it is very likely that the models  
280 do underestimate the snow influence.

281

### 282 *c. Origin of the snow cover dipolar variability in November*

283 To determine the origin of the dipolar snow cover anomalies, November SLP and  
284 2m air temperature anomalies are regressed onto the (standardized) MCA time series of  
285 November SCE, referred to as MCA-snow (Fig. 4). For the CMIP5 models, we only  
286 consider the four models (CanESM2, MPI-ESM, GISS-E2-R and CESM-BGC) that are  
287 consistent with observations and show the multi-model average of the regression  
288 patterns, while the number of models with a regression of the same sign documents  
289 their robustness, and provides a measure of inter-model spread.

290 The SLP anomalies associated with the snow dipole in both observations (Fig. 4a)  
291 and models (Fig. 4b) are characterized by a large anticyclonic anomaly over the Urals  
292 and a depression over Europe. The SLP pattern shares some similarity with the Eurasian  
293 pattern type 1 (Barnston and Livezey, 1987), the Scandinavian pattern (Bueh and

294 Nakamura 2007), the Russian pattern (Smoliak and Wallace, 2015) or the anomalies in  
295 Ural Blocking conditions (Luo et al., 2016). A similar pattern was also reported to result  
296 from the October SCE response (Cohen et al., 2014b). We will refer to this atmospheric  
297 patterns as the Scandinavian pattern (SCA) in the following. Figure 4 illustrates that  
298 warm (cold) air temperature anomalies are associated with negative (positive) SCE  
299 anomalies, consistent with the warm (cold) advection by the anomalous atmospheric  
300 circulation, as in the Greenland, Barents and Kara Seas that are affected by warm  
301 advection from the Norwegian Sea.

302         In observations, a dipolar SCE pattern similar to that in Fig. 3a and a SCA-like SLP  
303 pattern is also obtained as first MCA mode of simultaneous SLP and SCE anomalies in  
304 November, with 42.1% of squared covariance fraction (SCF), as shown in (Fig. 5a), while  
305 an AO influence onto the snow cover is only obtained as mode 3 (SCF = 11.6%). This is  
306 consistent with the first REOF of November SLP, which corresponds to the SCA (Fig. 6a).  
307 In December, however, the simultaneous covariability between SLP and SCE is  
308 dominated by the AO (SCF=55.1%, Fig. 5b), which decreases the advection from the  
309 relatively warm ocean toward the cooler Eurasian Continent. It also shifts southward  
310 the precipitation associated with the Atlantic stormtrack (Hurrell, 1995), which  
311 increases the SCE over Europe. We also see negative SCE anomalies east of the Caspian  
312 Sea associated with warm advection from the Mediterranean region.

313         On the other hand, the MCA suggests that, in most of the four models, the AO  
314 already has the largest impact on snow cover in November (Fig. 5c), with a much larger  
315 impact downstream of Europe, as shown by the positive anomalies over Eastern Siberia.  
316 Only CESM1 simulates the SCA pattern and its dipolar snow cover signature as first MCA  
317 mode (not shown). In fact, the first REOF of November SLP is also AO-like in all models  
318 (Fig. 6b). To establish its robustness, we have used as above distinct 36-yr chunks from

319 each control simulation, to reproduce the observed sampling. The SCA and AO are  
320 identified using the largest spatial pattern correlation with the observed SCA (November  
321 REOF1) and AO (November REOF3), respectively. The AO variance fraction is  
322 systematically larger than observed (Fig. 6c, yellow), while the SCA one is smaller (Fig.  
323 6c, red). This is consistent with the larger role of the SCA in the observation, when  
324 compared to model simulations, and it can be explained by either natural atmospheric  
325 variability or model biases. Indeed, CMIP5 models use relatively coarse horizontal  
326 resolutions, and are known to underestimate winter blocking episodes (Dawson et al,  
327 2012), leading to an overestimation of the NAO regimes (Cattiaux et al., 2013).

328

#### 329 **4. Processes of the November snow cover influence**

##### 330 *a. Role of Siberian snow cover*

331 The relative importance of the two poles of the November SCE dipole can be  
332 analyzed using two indices: the mean SCE anomalies over eastern Europe (20°E-58°E,  
333 48°N-60°N) and over eastern Siberia (70°E-140°E, 43°N-56°N). A bivariate regression of  
334 SLP anomalies in December on these two indices shows significant SLP anomalies in the  
335 observations (Figs. 7a and 7b), with negative SLP anomalies off Western Europe and  
336 positive anomalies over the polar cap. However, the eastern Siberia pole has the largest  
337 and most significant influence on SLP, and its impact is more AO-like. In the four models  
338 (Figs. 7c and 7d), Siberian SCE anomalies also have a larger AO-like influence on SLP,  
339 while European SCE is linked to a weak SLP dipole between Greenland and Scandinavia.  
340 Therefore, the most robust signal seems to be linked to the Siberian SCE influence,  
341 which is consistent with the reported influence of October snow cover (Saito and Cohen,  
342 2003).

343

344 *b. Associated surface changes*

345 The influence of surface conditions is evaluated using SCE and SIC regressions  
346 onto MCA-snow in Fig. 8. The November SCE anomalies (Fig. 8c,d) are preceded in  
347 October (Fig. 8a,b) and followed in December (Fig. 8e, f) by similar, but smaller,  
348 anomalies over eastern Siberia, which is consistent with the snow cover persistence  
349 over that region (Déry and Brown, 2007), and reflected in the large correlation (around  
350 0.5) between October and November SCE (see Fig. S1). European SCE anomalies are also  
351 present from October in the models, but not in observations. A significant retreat of the  
352 sea ice edge in the Barents Sea is also found for both models and observations in  
353 October and November, which is also visible in December in the models.

354 The surface heat flux in lead and lag conditions can be used to discuss the  
355 processes leading to the atmospheric circulation response. The heat flux preceding the  
356 SCE is dominated by the atmospheric forcing of the snow cover, as for SST anomalies,  
357 while the heat flux lagging the SCE should primarily reflect the heat flux directly forced  
358 by the SCE (the thermodynamical component), although it could be strongly affected by  
359 the surface heat flux intrinsically associated with the atmospheric response (hereafter  
360 the dynamical heat flux component); at lag 0, both effects play a role and may even  
361 cancel (Frankignoul et al. 1998). Since the surface heat flux responds rapidly to the  
362 surface conditions (simultaneously on monthly timescale), one can use in-phase  
363 relations to estimate the (thermodynamical) heat flux driven by the SCE anomalies, if  
364 the (larger) dynamical component is removed. To do so, we first calculate the heat flux  
365 by adding surface radiative and turbulent fluxes. A standardized atmospheric index,  
366 referred to as ATM, was computed by projecting the November SLP anomalies over  
367 30°N-90°N 80°W-180°E onto the SCA-like patterns shown in Fig. 4. The dynamical heat  
368 flux component corresponding to one standard deviation of the MCA-snow index is

369 obtained by regressing the heat flux anomalies onto ATM, multiplied by the correlation  
370 between ATM and MCA-snow (shown in Fig. S2). The total heat flux anomaly associated  
371 with the SCE pattern in Fig. 3a is given by the regression of the heat flux onto MCA-snow  
372 (shown in Fig. S3), while the difference of the two (Figs. 9a and 9b) is an estimate of the  
373 thermodynamical effect. Figs. 9c-d illustrate such thermodynamical component of the  
374 heat flux integrated over three boxes (see purple boxes in Fig. 9a-b) located over Siberia,  
375 Europe, and the Barents and Kara Seas. The location of the boxes was adjusted to  
376 capture the snow and sea-ice influences in models and observations.

377         In November, the heat flux changes induced by the snow cover are downward  
378 over a wide latitudinal band in central Siberia from lake Balkhash to Sakhalin Island in  
379 ERA-Interim and models (Fig. 9a-b), although the results are noisy in ERA-Interim. This  
380 is consistent with a net cooling effect of positive snow cover anomalies, as the larger  
381 surface albedo leads to more reflected shortwave radiation, and as the surface may be  
382 more insulated from the warmer soil if the snow depth also increases (Orsolini et al.,  
383 2016). The cooler surface temperature results in a dominant reduction of longwave  
384 radiation and sensible heat flux. However, the turbulent fluxes have a larger  
385 contribution in models, while the longwave and shortwave components dominate in  
386 observations (Fig. 9c and 9d). Conversely, the heat flux anomalies are upward in ERA-  
387 Interim over eastern Europe and Scandinavia where the SCE decreases, while in models,  
388 there is almost no net heating effect. Interestingly, over the Barents-Kara Seas, the heat  
389 flux is mainly upward over open-water in the Nordic Seas, which suggests a large  
390 heating of the atmosphere where the sea ice has retreated in November. This is  
391 consistent with an active influence of SIC anomalies onto the lower troposphere.  
392 However, while the total heat flux release over the Barents-Kara Seas is dominant in  
393 ERA-Interim, it is smaller and less robust in models. The same analysis applied to the

394 December heat flux provides comparable results over Europe and Siberia (see Fig. S4),  
395 but the heating over the Barents-Kara Seas is larger in models, while a net cooling is  
396 obtained in observations. This is because the sea-ice anomalies persist in December in  
397 models (see Fig. 8f), while they vanish in ERA-Interim (Fig. 8e).

398 In summary, the diabatic forcing of SCE anomalies is consistent in models and  
399 ERA-Interim, with cooling when the SCE increases. However, the diabatic heating from  
400 the SIC anomalies over the Barents-Kara Seas is larger, but it is also less robust than the  
401 one associated with SCE. As the surface heat flux anomalies are not assimilated in ERA-  
402 Interim and largely depend on the model physics, these results might be model  
403 dependent.

404

#### 405 *c. Troposphere-stratosphere coupling*

406 We calculated the regressions of the SLP (Fig. 10), zonal-mean temperature and  
407 geopotential height (Fig. 11) onto November MCA-snow, from October to January. In  
408 observations, the November SCE anomalies are preceded in October by a small  
409 anticyclone centered over the northern coast of Siberia (Fig. 10a), as in Cohen et al.  
410 (2002). In November, one month later, the SCA pattern (Fig. 10c) is visible, with cold  
411 tropospheric anomalies over Eurasia between 40°N and 60°N, above the positive SCE  
412 anomalies, and warm tropospheric anomalies at 78°N, at the location of the Barents-  
413 Kara Seas (Fig. 4). The zonal mean anomalies are largely barotropic below 300-hPa,  
414 which illustrates the main role of the tropospheric eddies in settling the SCA pattern.  
415 The anomalous anticyclone over Eurasia has been interpreted as a response to October  
416 Siberian snow cover, the snow-induced cooling acting to reinforce and expand westward  
417 the Siberian High (Cohen et al., 2007; Jeong et al., 2011; Orsolini et al., 2013). However, it  
418 can also be interpreted as a result of the stationary Rossby wave induced by the

419 anomalous turbulent heat flux from the sea ice retreat in the Barents-Kara Seas (e.g.  
420 Honda et al. 2009; Garcia-Serrano et al. 2015), or as internal atmospheric variability  
421 since simultaneous relations primarily show the SCE forcing by the SCA. In the lower  
422 stratosphere, there is a warming over the polar cap (75°N-90°N, between 300-hPa and  
423 100-hPa) and positive geopotential height anomalies above (Fig. 11a) that depicts a  
424 weakening of the polar vortex. In December, one month later, a barotropic negative  
425 NAO/AO pattern appears in the Euro-Atlantic region (Fig. 10e), while the polar vortex is  
426 further weakened, with stratospheric temperature anomalies above 100 hPa that are  
427 only significant between 40°N and 65°N (Fig. 11c). The regressions are similar in  
428 January, with the SLP anomalies projecting on the AO (Fig. 10g), and stronger zonal-  
429 mean geopotential height and temperature anomalies (Fig. 11e).

430 In the CMIP5 models, the atmospheric anomalies in October (Fig. 10b), which  
431 precedes by one month the SCE anomalies, show alternating trough and ridges from the  
432 North Atlantic to south-eastern Asia, with anticyclonic anomalies over the Urals and a  
433 depression over Northern Europe, clearly indicative of a stationary wave and already  
434 reminiscent of the SCA pattern. In November, the anomalies are more complex and  
435 larger, with a dominant anticyclonic circulation over the Urals extending into the Arctic  
436 (Fig. 10d), so that the Siberian High is clearly intensified and shifted westward, while the  
437 SLP response is AO-like in December and, to a lesser extent, in January. The temperature  
438 anomalies show a large warming in the lower troposphere north of 70°N (Fig. 11b, d)  
439 from November to December, and display an important warming in the polar  
440 stratosphere that persists into January only in the lowermost stratosphere at 200-hPa.  
441 The warm anomalies are rather baroclinic in the polar troposphere, which is consistent  
442 the influence of Arctic SIC reduction noted in Cattiaux and Cassou (2013). In November  
443 and December, there are also cold temperature anomalies below 400-hPa south of the

444 positive SCE anomalies, likely associated with the cold temperature found over Siberia  
445 where the snow cover increases (Fig. 10b,d). In models, both the tropospheric NAO/AO  
446 pattern and the anomalies in the stratosphere are smaller during January, but they are  
447 still significant (Fig. 10h and 11f).

448         The troposphere-stratosphere coupling is further illustrated by the polar cap  
449 temperature (65°N-90°N) regression onto the MCA-snow index in Fig. 12. For  
450 observations, the daily air temperature was used, while only monthly data was available  
451 for models. The observations show a warming in the lower stratosphere between 200-  
452 hPa and 70-hPa from December to February, as found by Cohen et al. (2014b) and  
453 Orsolini et al. (2016), but it is only 10% significant for a few days in early December and  
454 January. There are also hints of downward propagation in late December and late  
455 January. In models, the polar cap temperature anomalies are only half the ones  
456 observed, the timing is different as the warming starts in November, one month earlier,  
457 and the downward propagation is faster in the stratosphere with little penetration into  
458 the troposphere.

459         In summary, the diabatic heating from the November SCE and, possibly, SIC  
460 anomalies is associated with a stationary wave pattern that weakens the polar vortex.  
461 Particularly in observations, the AO changes obtained one and two months later are  
462 consistent with the downward propagation of polar vortex weakening. Next, we will  
463 establish the relative importance of the SIC and SCE anomalies.

464

#### 465         *d. Link with sea ice anomalies*

466         In order to compare the role of SIC and SCE, we also perform a MCA using SIC  
467 over the Barents-Kara Sea (65°N-85°N; 15°E-100°E) in November and SLP in December.  
468 We additionally perform a MCA using both November SIC and SCE concatenated into a

469 single predictor field, with SLP as predictand field. The results are summarized in Table  
470 2. When only using November SIC as predictor, the NSC is highly significant, but the  
471 correlation R is lower than when using SCE, and not significant at the 10% level, as in  
472 Garcia-Serrano et al. (2015; see also Fig. S5). On the other hand, using concatenated SCE  
473 and SIC predictors is as significant as with SCE alone, and the MCA patterns (Fig. 13a)  
474 show that the snow dipolar anomalies and the sea ice retreat in the Barents-Kara Seas  
475 precede a negative AO-like pattern in December, which is consistent with previous  
476 results (Fig. 8), but for larger SIC changes. Interestingly, SCE and SIC seem to contribute  
477 similarly to the SLP response in Fig. 13. Indeed, projecting SIC anomalies onto the SIC  
478 part of the MCA covariance map (referred to as MCAcat\_SIC) and SCE anomalies onto the  
479 SCE part (referred to as MCAcat\_SCE) yields two well correlated time series (0.58,  
480 significant at the 5% level) that compare well with the atmospheric December MCA time  
481 series (Fig. 13b).

482         In order to evaluate the relative influence of the SCE and SIC pattern, we used the  
483 time series associated with the SCE and SIC fields in the SCE/SLP (MCA-snow) and  
484 SIC/SLP (referred to as MCA-SIC) individual MCA, respectively, to separate more clearly  
485 the SIC and SCE influences. These two times series have a correlation of 0.42, and a  
486 bivariate regression of the SLP using these two time series shows little multicollinearity  
487 (variance inflation factor of 1.4). The regression slopes (Fig. 14) show that the SCE holds  
488 a larger signal in observations, which is consistent with the higher correlation in the  
489 MCA analysis (see Table 2). The SIC has a similar influence, but its amplitude is twice  
490 smaller, and it is less significant. These results are not substantially modified when using  
491 other indices for SCE or SIC.

492         The concatenated MCA yields similar results for the four models, with a SCE  
493 dipole and a decrease of SIC in November preceding the December AO (not shown),

494 although the NSC and correlation are much lower, and adding SIC to SCE (or considering  
495 SIC alone) strongly degrades the levels of significance (Table 2). Yet, the correlation  
496 between the MCAcat\_SCE and MCAcat\_SIC time series (Table 3) is significant in each  
497 model, even if it is lower than in observations, which can be explained by the different  
498 sampling, the smaller SCA occurrence, or model biases such as the colder mean state in  
499 pre-industrial climate, which allows less Barents-Kara SIC variability. However, these  
500 significance tests are biased since the four models were selected based on their  
501 response to SCE, not to SIC, and other CMIP5 models are more sensitive to SIC (Garcia-  
502 Serrano et al. 2016).

503         The same analysis was conducted using SIC anomalies in early autumn  
504 (September or October) together with November SCE (Table S2), which provides  
505 significant results only when using October SIC, with patterns as in Fig. 13, but smaller  
506 NSC and R. We also repeated the analysis using November SIC/SCE and SLP in January  
507 and February (Table S3), as the stratospheric pathway is also important during late  
508 winter (Kim et al., 2014; Jaiser et al., 2016), but the MCA results are much less significant  
509 in the observations.

510

#### 511         *e. Link with the Scandinavian pattern*

512         The upward influence of tropospheric planetary waves into the stratosphere due  
513 to atmospheric dynamics, such as during blocking situations, can also explain that the  
514 SCA is followed by an AO-like pattern one month later, without any influence of surface  
515 diabatic heating (Kuroda and Kodera, 1999; Takaya and Nakamura, 2008; Martius et al.,  
516 2009; Woollings et al., 2010). To test the influence of such troposphere-stratosphere  
517 coupling, we use an MCA with Eurasian SLP (0E-150E, 45N-85N), Eurasian SCE, and  
518 Barents/Kara SIC in November concatenated as the predictor field, and Northern

519 Hemisphere SLP in December as the predictand field. For the sake of simplicity, the  
520 ENSO variability was not removed in the analysis. In both observations and models, the  
521 results of this MCA are strongly significant (Table 2), and the covariance maps are  
522 similar to Fig. 13, with the homogeneous SLP covariance map in November resembling  
523 the SCA (not shown).

524 We next examine the time series of the three November predictors (SCE dipole,  
525 Barents/Kara SIC, SCA). The time series associated with the SCE and SIC fields are  
526 obtained as before from the SCE/SLP (MCA-snow) and SIC/SLP (MCA-SIC) individual  
527 MCAs, while the SCA index is given by the first rotated EOF of the Eurasian SLP (0E-  
528 150E, 45N-85N) in November. To distinguish the impact of each predictor, a  
529 multivariate regression of the December SLP on the three predictors is done, noting that,  
530 despite the large correlation between predictors, multicollinearity is limited (variance  
531 inflation factors < 2.0). The results (Fig. 15a-c) again show that the SCE dipole has the  
532 largest influence onto SLP in December, while the SIC provides weaker, but significant  
533 anomalies as in the bivariate regression in Fig. 14. The SCA seems to be also important  
534 for the SLP over the British Isles or Alaska, but the anomalies are weaker and not  
535 significant. A similar multivariate regression using an AO index, as given by the first EOF  
536 of December SLP is shown in Fig. 15d. Again, the SCE appears to be the best predictor of  
537 the AO, followed by the SIC, while the SCA has the lowest  $R^2$ . Taking the three indices as  
538 predictors with a multivariate regression only slightly improves the variance explained  
539 by the SCE alone. In the four models (Fig. 15d, symbols using the right vertical axis), the  
540 same analysis also shows that the SCE dipole still plays the dominant role in three  
541 models, while the SIC has a dominant influence only in one model (CanESM). In all  
542 models, the SCA pattern also appears as good predictor of the AO. This suggests that, in  
543 these models selected based on their response to SCE, internal atmospheric dynamical

544 processes may also explain the statistical relationship found among SCE, SIC and the  
545 atmosphere one month later, hence that the influence of SCE and SIC is underestimated.  
546 These conclusions are not substantially modified when using other indices for the AO,  
547 the snow dipole or the Barents-Kara SIC anomalies.

548

## 549 **5. Discussions and Conclusion**

550 We have investigated the links between Eurasian SCE and the atmosphere in  
551 observations during 1979-2014 and CMIP5 models. We found that a dipole of snow  
552 cover anomalies in November with positive (negative) snow cover anomalies over  
553 eastern Siberia (eastern Europe) precedes a negative AO-like pattern in December, one  
554 month later. The largest statistical links are found when considering November SCE, as  
555 in Orsolini et al. (2016), but other studies focus more on October snow cover (Cohen and  
556 Entekhabi, 1999; Cohen et al. 2007; Cohen and Jones 2011; Handorf et al. 2015). Lagged  
557 regression actually reveals that the November SCE is related to similar anomalies in  
558 October, but statistical significance is too limited with the MCA using October SCE. The  
559 choice of the data set, the methodology and the period considered might explain this  
560 discrepancy (see Appendix A). The CMIP5 models, in general, fail to simulate this  
561 potential effect of snow cover. Nevertheless, a weaker, but similar, relationship between  
562 the SCE and the AO is present in four models: CanESM, MPI-ESM-LR, GISS-E-R and  
563 CESM-BGC.

564 The models and ERA-Interim indicate that downward (upward) heat flux  
565 anomalies are simulated over positive (negative) snow cover anomalies over Siberia  
566 (Europe) during November. We verified that eastern Siberia pole of the snow dipole  
567 anomalies has the best relationship with the AO one month later both in observations  
568 and models, so that the SCE over Siberia seems to have the largest influence. The

569 diabatic cooling of the troposphere over Siberia is consistent with the intensification and  
570 westward expansion of the Siberian High. This may lead to a polar vortex weakening  
571 from November to January driven by upward planetary wave activity flux, as found  
572 previously in observations (Saito et al. 2001; Handorf et al. 2015; Furtado et al. 2016)  
573 and in sensitivity experiments using SCE anomalies (Gong et al., 2004; Fletcher et al.,  
574 2009; Peings et al., 2012; Orsolini et al. 2013; Orsolini et al. 2016). Here, we show that  
575 the same process can be verified qualitatively using multi-centennial control climate  
576 model simulations, although the SCE influence is much weaker.

577         The atmospheric pattern responsible for the variability of the snow cover dipole  
578 is the Scandinavian pattern (SCA, as in Bueh and Nakamura, 2007), with a large  
579 anticyclone over the Urals. Such anticyclone leads to northerly cold advection east of the  
580 anticyclone, bringing cold air over Siberia, and southerly warm advection over Central  
581 Europe and the Barents and Kara Seas. The SCA forcing explains that the Barents/Kara  
582 SIC and Eurasian SCE are largely correlated (Wegmann et al., 2015; Furtado et al., 2016).  
583 We find that the models produce less frequent SCA-like and more frequent AO-like  
584 events, possibly linked to blocking processes that are not well simulated in low  
585 resolution models (Dawson, 2012), but this could also be due to natural atmospheric  
586 variability. Deficiencies in the simulation of the SCA characteristics in models might  
587 therefore explain the weaker SCE influence in models. In addition, the upward heat flux  
588 driven by a retreat of the sea ice in the Barents-Kara Seas is weaker and less robust in  
589 the models than in ERA-Interim, perhaps explaining why the SIC influence is also  
590 underestimated in the four models that simulate the SCE impacts.

591         A MCA using SLP and combined SCE and SIC suggests that November SCE and SIC  
592 forcing provide similar covariability with the December AO in observations. However, a  
593 bivariate regression reveals that the SCE dipole is a much better predictor than the

594 Barents-Kara SIC anomaly. As the SCE and the SIC variability are linked, both fields  
595 might constructively interfere to weaken the polar vortex, as suggested in Cohen et al.  
596 (2014a), although the surface forcing from the snow cover anomalies might be  
597 dominant. On the other hand, the November SIC in models has an impact on the AO in  
598 only one model, perhaps because they were selected based on their representation of  
599 the SCE influence. When investigating more systematically the links between Greenland-  
600 Barents-Kara SIC and the NAO/AO in CMIP5 models, Garcia-Serrano et al. (2016) did  
601 find a robust SIC influence, but they noted that the timing or the processes for the SIC  
602 influence are model dependent. Here, the lack of links between November SIC and  
603 December atmosphere may result from our selection of the models based on their  
604 representation of the SCE impact (and not SIC impact), and also from the model  
605 averaging that may mix different behavior among models. The weaker SCE influence in  
606 models and the lack of links between the SCE and SIC is consistent with the  
607 underestimated troposphere-stratosphere coupling in models, as found in Furtado et al.  
608 (2015). However, it can also be explained by the poor simulation of the SCA variability,  
609 the colder climate in preindustrial control simulation, or natural climate variability.

610         A better understanding of the coupling between land snow cover, Arctic sea ice,  
611 and the atmosphere using dedicated climate model experiments would be necessary to  
612 properly assess the causality links and better discriminate between their influence on  
613 the winter AO. Nonetheless, the methodology used here could be applied to climate  
614 projection of the 21<sup>st</sup> century in order to investigate how the polar amplification of  
615 global warming will modify the links between the atmosphere and Arctic surface  
616 conditions.

617

618

619

## 620 **Appendix : October snow cover influence**

621

622         The influence of October SCE on the atmosphere is discussed by using the MCA  
623 results, when SLP lags by one month, although statistical significance is limited (see Fig.  
624 1). The covariance maps (Fig. A1a) show that increasing October SCE over northern  
625 Eurasia precedes a SLP pattern in November that has some resemblance with the SCA,  
626 plus a deeper Aleutian low. This differs from the negative AO found later, from  
627 December to February. It might be due the snow data used, as many previous studies  
628 used a more integrated snow index, such as the Eurasian snow cover areal extent (e.g.  
629 Cohen et al. 2007; Cohen and Fletcher 2007). It could be due to differences in  
630 methodology, as Furtado et al. (2016) used multivariate EOF. It could also be due to non-  
631 stationarity (Peings et al., 2013). For instance, Cohen et al. (2007) considered the 1948-  
632 2004 period, Cohen and Fletcher (2007) the 1972-2005 one, while we focus on 1979-  
633 2014.

634         To investigate the possible influence of non-stationarity, we performed the MCA  
635 in different sub-periods (Table A1). The most significant influence of October snow  
636 cover on SLP is found for November in the 1979-2005 period, as used in Cohen and  
637 Fletcher (2007); the MCA mode is also significant for December SLP, with a MCA pattern  
638 (Fig. A1d) sharing a large similarity with previous studies (i.e. Handorf et al., 2015).  
639 However, the levels of significance are limited when the DJF atmosphere is considered. If  
640 1979-2011 or 1979-2014 is used, significance is lost. Hence, the detected influence of  
641 the October snow cover is sensitive to the period.

642

643

645 The research leading to these results has received funding from the Blue-Action project  
646 (the European Union's Horizon 2020 research and innovation programme, Grant  
647 727852). Javier García-Serrano also received funding from H2020-funded DPETNA  
648 grant (MSCA-IF-EF 655339). We thank the European Center for Medium Range Weather  
649 Forecast for providing the ERA-Interim reanalysis, the Rutgers University for providing  
650 the observed snow cover fields, the National Snow and Ice Data Center for providing the  
651 sea ice extent. For their role in producing, coordinating, and making available CMIP5  
652 model outputs, we acknowledge the climate modeling groups, the World Climate  
653 Research Programme's Working Group on Coupled Modelling and the Global  
654 Organization for Earth System Science Portals. This study benefited from the IPSL  
655 mesocenter facility which is supported by CNRS, UPMC, Labex L-IPSL, which is funded  
656 by the ANR (Grant #ANR-10-LABX-0018), and by the European FP7 IS-ENES2 project  
657 (Grant #312979).

884

885 TABLE A1. Statistics of the MCA using October snow cover and SLP in following months,  
 886 using different time periods (79-05 : from 1979 to 2005 ; 79-11 : from 1979 to 2011 and  
 887 79-14 : from 1979 to 2014), and atmospheric months (NOV : November ; DEC :  
 888 December ; DJF : December-January-February). The level of statistical significance is  
 889 given in parentheses.

890

Period	SLP season	NSC	R
79-14	NOV	1.3 (10%)	0.70 (13%)
79-14	DJF	1.1 (29%)	0.63 (32%)
79-05	NOV	1.9 (3%)	0.83 (5%)
79-05	DEC	1.9 (6%)	0.80 (6%)
79-05	DJF	2.4 (6%)	0.71 (25%)
79-11	NOV	1.1 (27%)	0.77 (21%)
79-11	DEC	1.6 (9%)	0.71 (27%)
79-11	DJF	1.5 (11%)	0.66 (44%)

891

892

893

## 894 **Figures Caption**

### 895 **Figure 1 :**

896 Normalized squared covariance (NSC, contours, in %) for the first MCA mode between  
897 observed SLP and Eurasian snow cover, for each month in the atmosphere. The lag is  
898 positive when the snow cover leads SLP. The gray shading provides the level of  
899 statistical significance for NSC. The plus symbols indicate the atmospheric month and  
900 time lag where the level of significance for the correlation (R) is below 5%.

901

### 902 **Figure 2 :**

903 (a) Scatter plot of the confidence level, in %, of the normalized squared covariance, NSC,  
904 versus that of the correlation, R, for the first MCA mode between SLP and Eurasian snow  
905 cover. (b) Scatter plot of the spatial correlation between the SLP covariance map found  
906 in models and that of ERA-Interim, versus the spatial correlation between the snow  
907 cover covariance map found in models and that of ERA-Interim. The black indicates the  
908 results for SLP in December and SCE in November (one month lag). The blue indicates  
909 the results for SLP in November and SCE in October (one month lag). The red indicates  
910 the results for the SLP in January and SCE in November (two month lag). In (b), the bold  
911 symbols indicate levels of significance lower than 15% for both NSC and R.

912

### 913 **Figure 3 :**

914 (a) Homogeneous snow cover fraction (in %) and heterogeneous SLP (in hPa)  
915 covariance maps for the first MCA mode, for December SLP and November snow cover,  
916 when the snow cover leads by one month the atmosphere, in ERA-Interim. (b) Same as

917 (a), but using January SLP with a 2 month lag. (c), (d), (e), (f) and (g) same as (a) but for  
918 CanESM2, MPI-ESM, GISS-E2-R, CESM1-BGC and the mean of the four models,  
919 respectively. Note that the color scale is different for observation and models. (h) Box  
920 plots of the NSC and R statistics from the MCA using 36-yr periods extracted from the  
921 control runs of each models (1: CanESM2, 2:MPI-ESM, 3: GISS-E2-T and 4: CESM1-BGC),  
922 error bars show the 5% and 95% percentiles. The dashed horizontal lines show the NSC  
923 and R values in observations.

924

925 **Figure 4 :**

926 Regression of SLP (contours, in hPa) and 2m air temperature, (color, in K) on the MCA-  
927 snow index, in November, for (a) ERA-Interim and (b) the subset of four models. In (a),  
928 colors are masked if the level of significance is above 10% for observation. In (b), colors  
929 indicate anomalies of the same sign among the four models.

930

931 **Figure 5 :**

932 Homogeneous SLP (in hPa) and heterogeneous snow cover (in %) covariance maps for  
933 the first MCA mode, when the SLP and snow cover are simultaneous (no lag), for (a)  
934 November fields in ERA-Interim; (b) December fields in ERA-Interim and (c) November  
935 fields in the mean of the four models.

936

937 **Figure 6 :**

938 (a) REOF1 of November SLP (in hPa) in ERA-Interim. (b) Same as (a) for the model mean  
939 REOF1 using the four models. In (a), the variance fraction is given in parentheses. In (b),  
940 the minimum and maximum variance fraction among the four models is indicated in  
941 parentheses. (c) Box plots of the November variance (in %) explained by the SCA and

942 the NAO/AO in 36-yr chunks from the control runs of each models (1: CanESM2, 2:MPI-  
943 ESM, 3: GISS-E2-R and 4: CESM1-BGC); the error bars give the 5% and 95% percentiles,  
944 and the dashed horizontal lines the AO and SCA variance fraction in observations.

945

946 **Figure 7 :**

947 Regression of the December SLP in hPa onto (Left) European and (Right) Siberian snow  
948 anomalies, given by multivariate regression; for (upper) ERA-Interim and (lower) the  
949 subset of four models. In (a) and (b), colors are masked if the level of statistical  
950 significance is above 10%. In (c) and (d), colors indicate anomalies of the same sign  
951 among the four models.

952

953 **Figure 8 :**

954 Regression of the snow cover fraction (gray contours and color shading over continent,  
955 in %) and sea ice concentration (blue contours and color shading over the ocean, in %),  
956 onto the November MCA-snow index, for (a) ERA-Interim in October; (b) the four  
957 models in October; (c) and (d) Same as (a) and (b) for November; (e) and (f) same as (a)  
958 and (b) for December. The sea-ice concentration contour interval is 5% in observations,  
959 and 1% for models, the zero contour is removed. The thick gray contour provides the  
960 50% contour for climatological SIC.

961

962 **Figure 9 :**

963 November heat flux thermodynamical component, positive upward, in  $W m^{-2}$ , associated  
964 with the November MCA-snow index in (a) ERA-Interim and (b) the four models. The  
965 color scale is different over land and ocean to emphasize the changes over continental  
966 surfaces. Note the different contour intervals for ERA-Interim and models. (c,d)

967 Regressions of the shortwave (SW), longwave (LW), sensible (SH), latent (LH) and total  
968 (Tot) heat flux over the Siberia (SIB), Europe (EUR) and Barents-Kara Sea (B/K)  
969 integrated over boxes shown in (a) and (b) with histograms for (c) ERA-Interim and (d)  
970 the four models mean. In (d) the error bars indicate the minimum and maximum values  
971 among models.

972

973 **Figure 10 :**

974 Regression of the SLP, in hPa (contour interval 0.5 hPa), onto the MCA-snow index, (left  
975 column) ERA-Interim and (right column) models, in (a), (b) October; (c), (d) November;  
976 (e), (f) December and (g), (h) January . The thick black line indicates 5% significance for  
977 observations or anomalies of the same sign among the four models. The contour interval  
978 at -0.2 and 0.2 hPa was added for models.

979

980 **Figure 11 :**

981 Regression of the zonal-mean temperature (gray contours and color shading, in K) and  
982 geopotential height (blue contours, in m) onto the MCA-snow normalized index, for (left  
983 column) ERA-Interim and (right column) models, in (a), (b) November; (c), (d)  
984 December and (e), (f) January. Colors indicate zonal mean temperature (left) level of  
985 significance below 10% or (right) anomalies of the same sign among the four models.

986

987 **Figure 12 :**

988 Regression of the temperature over the polar cap (65°N-90°N) onto the MCA-snow  
989 normalized index, for (a) ERA-Interim and (b) models. The thick black lines indicate (a)  
990 level of significance below 10% or (b) anomalies of the same sign among the four  
991 models. Note the different contour intervals in (a) and (b).

992

993 **Figure 13 :**

994 (a) Snow cover (color over land, in %) and SIC (color over ocean, in %) homogeneous  
995 covariance map and SLP (in hPa) heterogeneous map for the first MCA mode using  
996 combined snow/sea-ice in November and SLP in December for ERA-Interim. (b) (black)  
997 MCAcat\_SCE, (red) MCAcat\_SIC and (green) atmospheric SLP yearly time series from the  
998 MCA (normalized).

999

1000 **Figure 14 :**

1001 Regression slopes of a bivariate regression of the December SLP (in hPa) for the (a)  
1002 MCA-snow, and (b) MCA-SIC indices. Colors indicate level of significance below 10%.

1003

1004 **Figure 15 :**

1005 Regression slopes of a multivariate regression of the SLP (in hPa) onto the (a) snow  
1006 dipole, (b) Barents-Kara Sea SIC and (c) SCA indices. In (a-c) colors indicate level of  
1007 significance below 10%. (d)  $R^2$  value of univariate regressions using the AO index as  
1008 predictand and snow dipole, Barents-Kara Sea SIC or SCA as predictor. ALL indicates the  
1009  $R^2$  when using the three indices in a multivariate regression. Note that the y-axis is  
1010 different for observation (bars, left axis) and models (symbols, right axis).

1011 The black symbols (bars) provide the results for models (observations), thick symbols  
1012 (bars) indicating level of significance of  $R^2$  below 10%.

1013

1014 **Figure A1 :**

1015 (a) Homogeneous October snow cover fraction (in %) and November heterogeneous SLP  
1016 (in hPa) covariance maps for the first MCA mode, when the snow cover leads by one

1017 month the atmosphere, for ERA-Interim during 1979-2014. (b) Same as (a) but for the  
1018 1979-2005 period. (c) Same as (a) but using the December SLP. (d) Same as (c) but for  
1019 the 1979-2005 period.

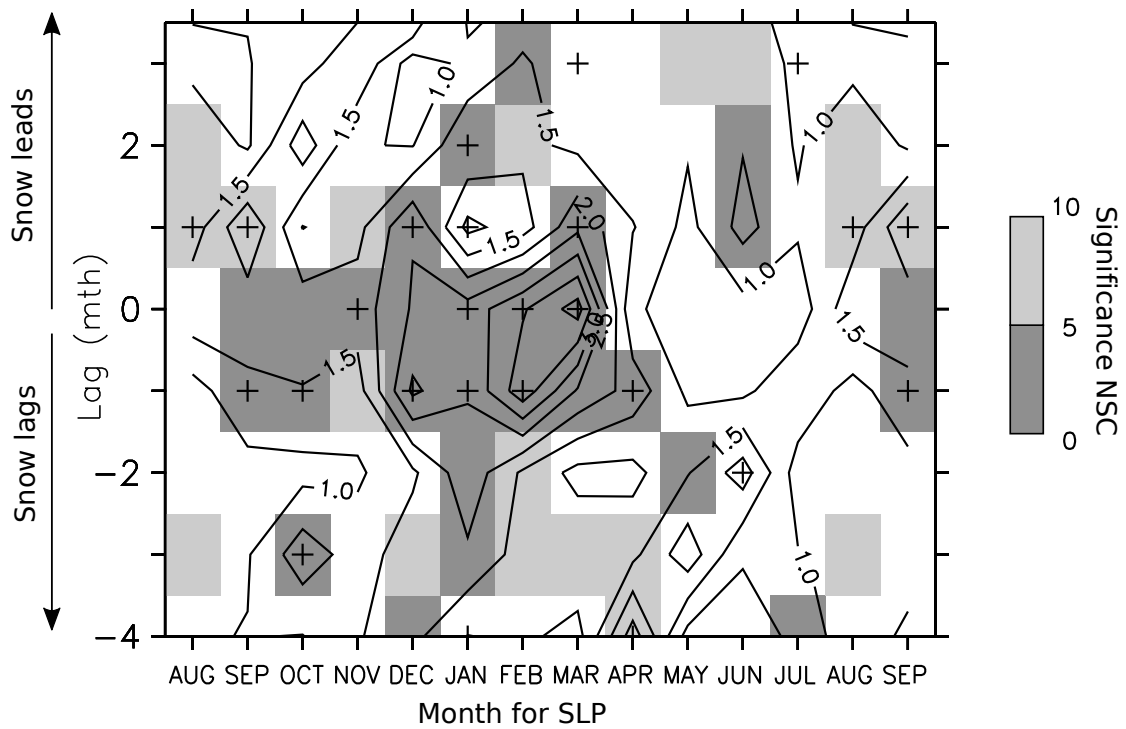

Fig. 1 : Normalized squared covariance (NSC, contours, in %) for the first MCA mode between observed SLP and Eurasian snow cover, for each month in the atmosphere. The lag is positive when the snow cover leads SLP. The gray shading provides the level of statistical significance for NSC. The plus symbols indicate the atmospheric month and time lag where the level of significance for the correlation (R) is below 5%.

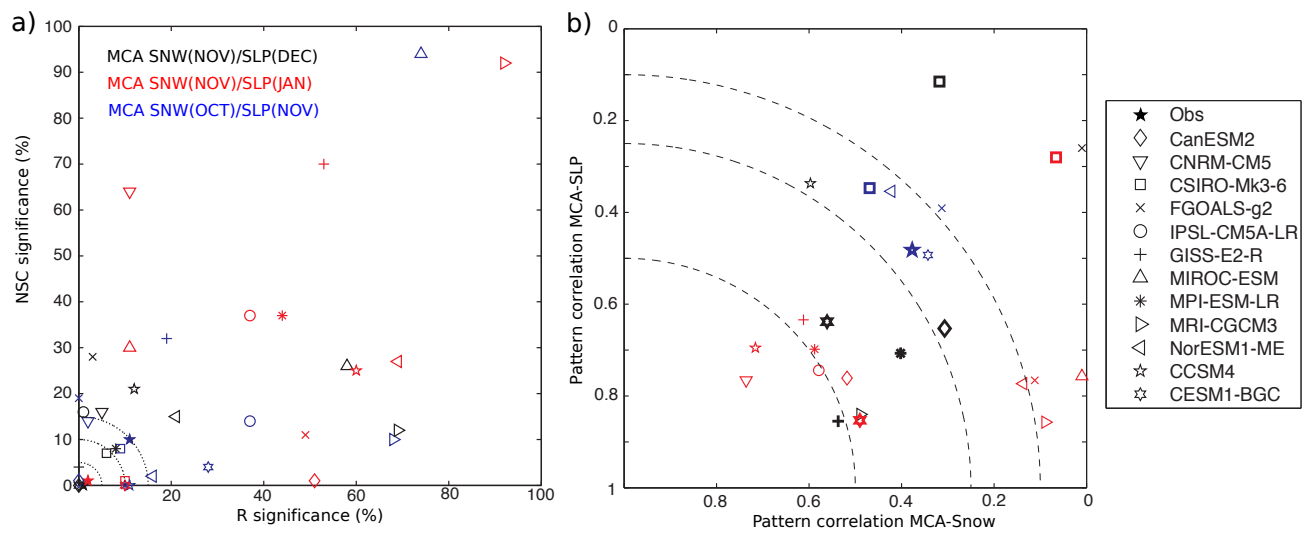

Fig. 2 : (a) Scatter plot of the confidence level, in %, of the normalized squared covariance, NSC, versus that of the correlation, R, for the first MCA mode between SLP and Eurasian snow cover. (b) Scatter plot of the spatial correlation between the SLP covariance map found in models and that of ERA-Interim, versus the spatial correlation between the snow cover covariance map found in models and that of ERA-Interim. The black indicates the results for SLP in December and SCE in November (one month lag). The blue indicates the results for SLP in November and SCE in October (one month lag). The red indicates the results for the SLP in January and SCE in November (two month lag). In (b), the bold symbols indicate levels of significance lower than 15% for both NSC and R.

Fig. 3 : (a) Homogeneous snow cover fraction (in %) and heterogeneous SLP (in hPa) covariance maps for the first MCA mode, for December SLP and November snow cover, when the snow cover leads by one month the atmosphere, in ERA-Interim. (b) Same as (a), but using January SLP with a 2 month lag. (c), (d), (e), (f) and (g) same as (a) but for CanESM2, MPI-ESM, GISS-E2-R, CESM1-BGC and the mean of the four models,

respectively. Note that the color scale is different for observation and models. (h) Box plots of the NSC and R statistics from the MCA using 36-yr periods extracted from the control runs of each models (1: CanESM2, 2:MPI-ESM, 3: GISS-E2-T and 4: CESM1-BGC), error bars show the 5% and 95% percentiles. The dashed horizontal lines show the NSC and R values in observations.

Fig. 4 : Regression of SLP (contours, in hPa) and 2m air temperature, (color, in K) on the MCA-snow index, in November, for (a) ERA-Interim and (b) the subset of four models. In (a), colors are masked if the level of significance is above 10% for observation. In (b), colors indicate anomalies of the same sign among the four models.

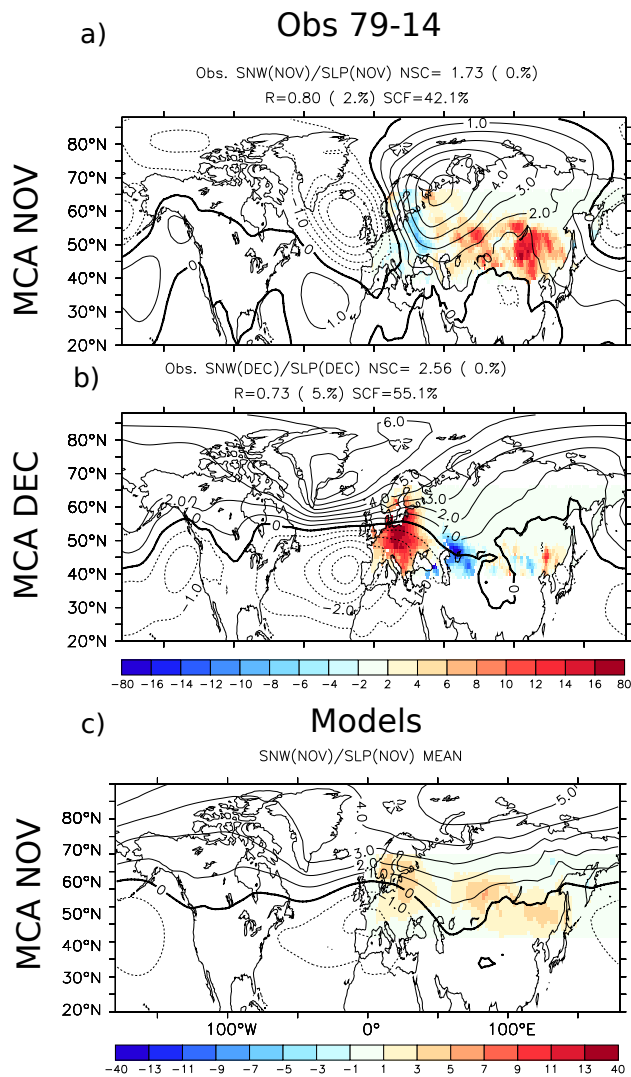

Fig. 5 : Homogeneous SLP (in hPa) and heterogeneous snow cover (in %) covariance maps for the first MCA mode, when the SLP and snow cover are simultaneous (no lag), for (a) November fields in ERA-Interim; (b) December fields in ERA-Interim and (c) November fields in the mean of the four models.

Fig. 6 : (a) REOF1 of November SLP (in hPa) in ERA-Interim. (b) Same as (a) for the model mean REOF1 using the four models. In (a), the variance fraction is given in parenthesis. In (b), the minimum and maximum variance fraction among the four models is indicated in parenthesis. (c) Box plots of the November variance (in %) explained by the SCA and the NAO/AO in 36-yr chunks from the control runs of each models (1: CanESM2, 2:MPI-ESM, 3: GISS-E2-R and 4: CESM1-BGC); the error bars give the 5% and 95% percentiles, and the dashed horizontal lines the AO and SCA variance fraction in observations.

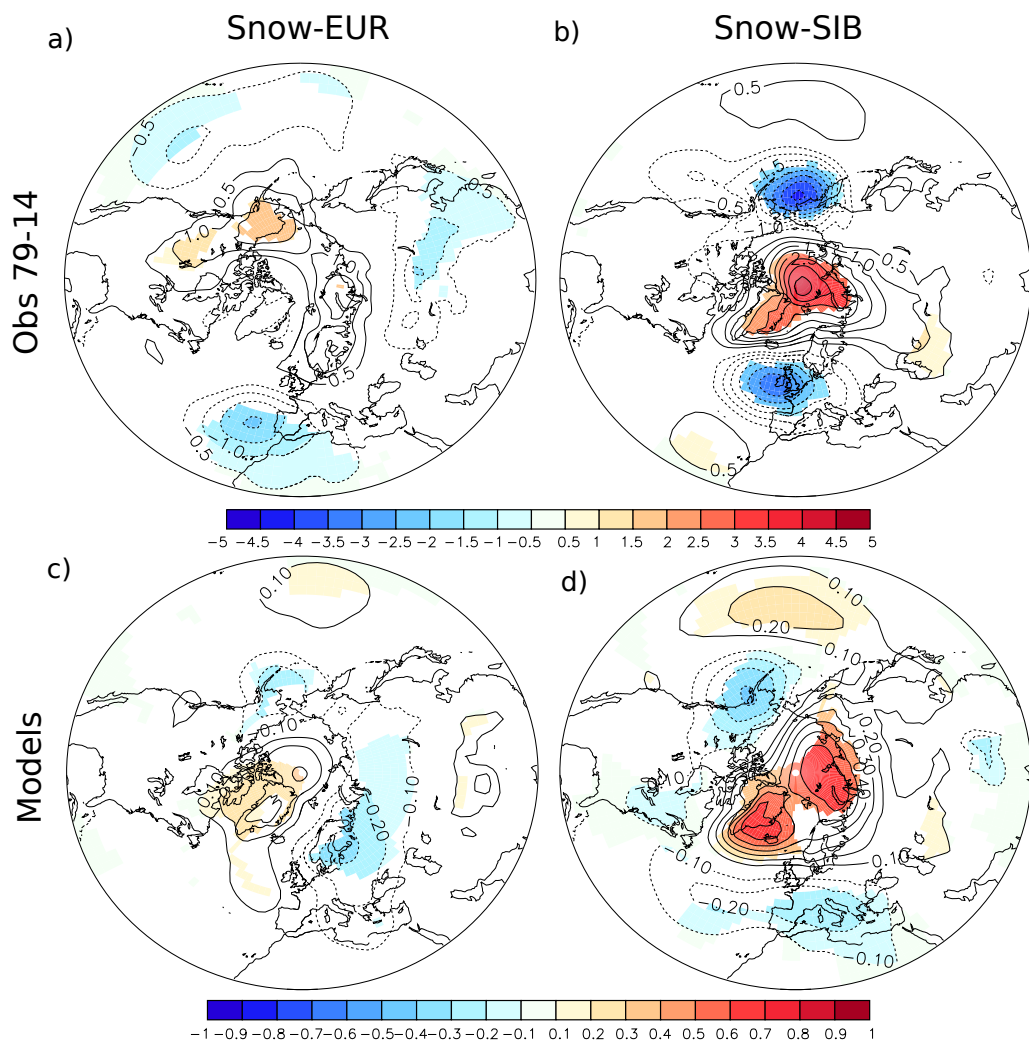

Fig. 7: Regression of the December SLP in hPa onto (Left) European and (Right) Siberian snow anomalies, given by multivariate regression; for (upper) ERA-Interim and (lower) the subset of four models. In (a) and (b), colors are masked if the level of statistical significance is above 10%. In (c) and (d), colors indicate anomalies of the same sign among the four models.

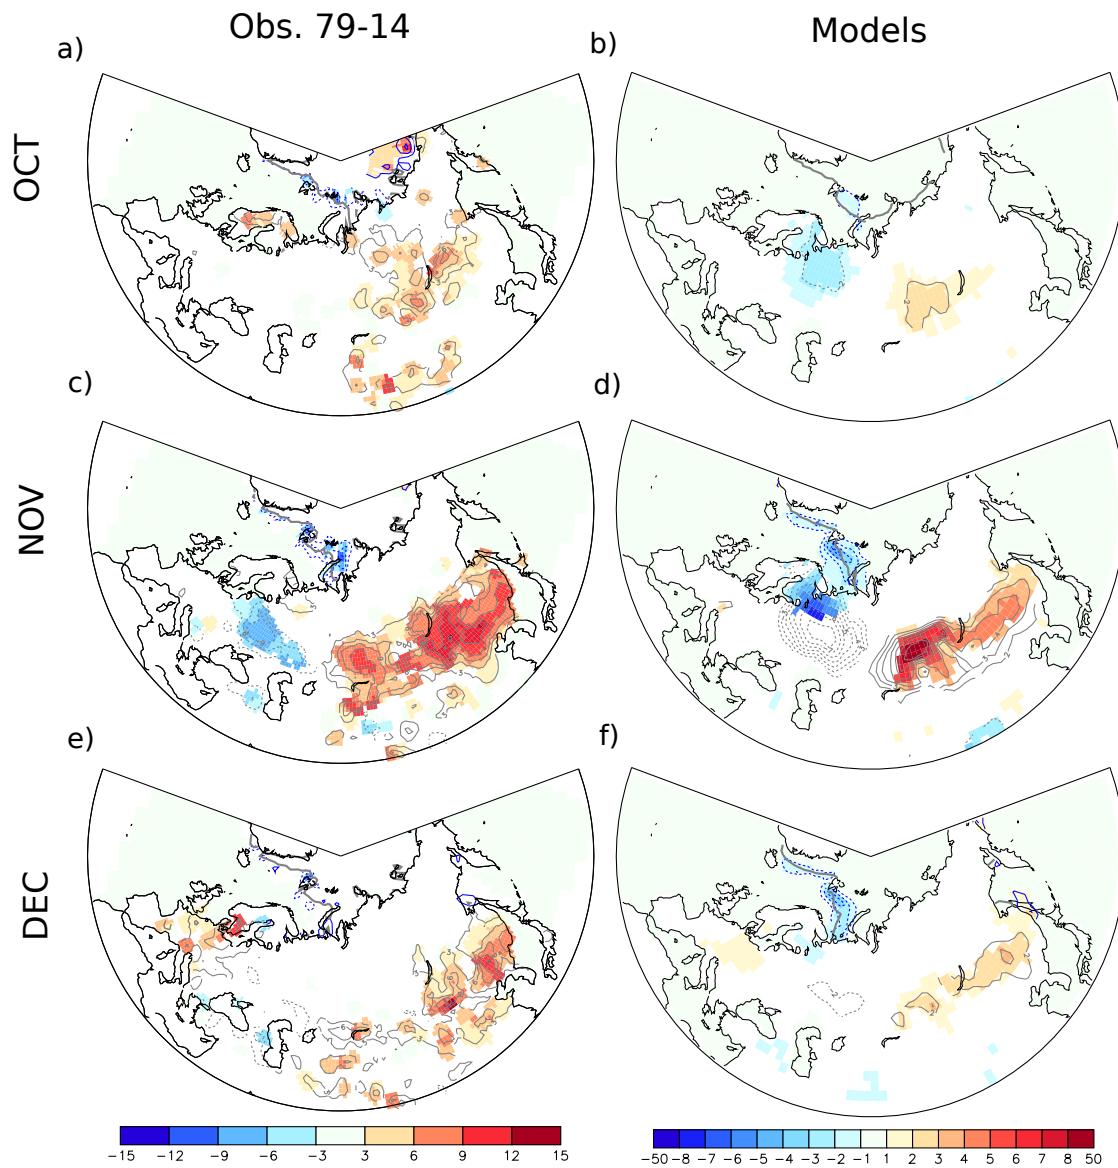

Fig. 8 : Regression of the snow cover fraction (gray contours and color shading over continent, in %) and sea ice concentration (blue contours and color shading over the ocean, in %), onto the November MCA-snow index, for (a) ERA-Interim in October; (b) the four models in October; (c) and (d) Same as (a) and (b) for November; (e) and (f) same as (a) and (b) for December. The sea-ice concentration contour interval is 5% in observations, and 1% for models, the zero contour is removed. The thick gray contour provides the 50% contour for climatological SIC.

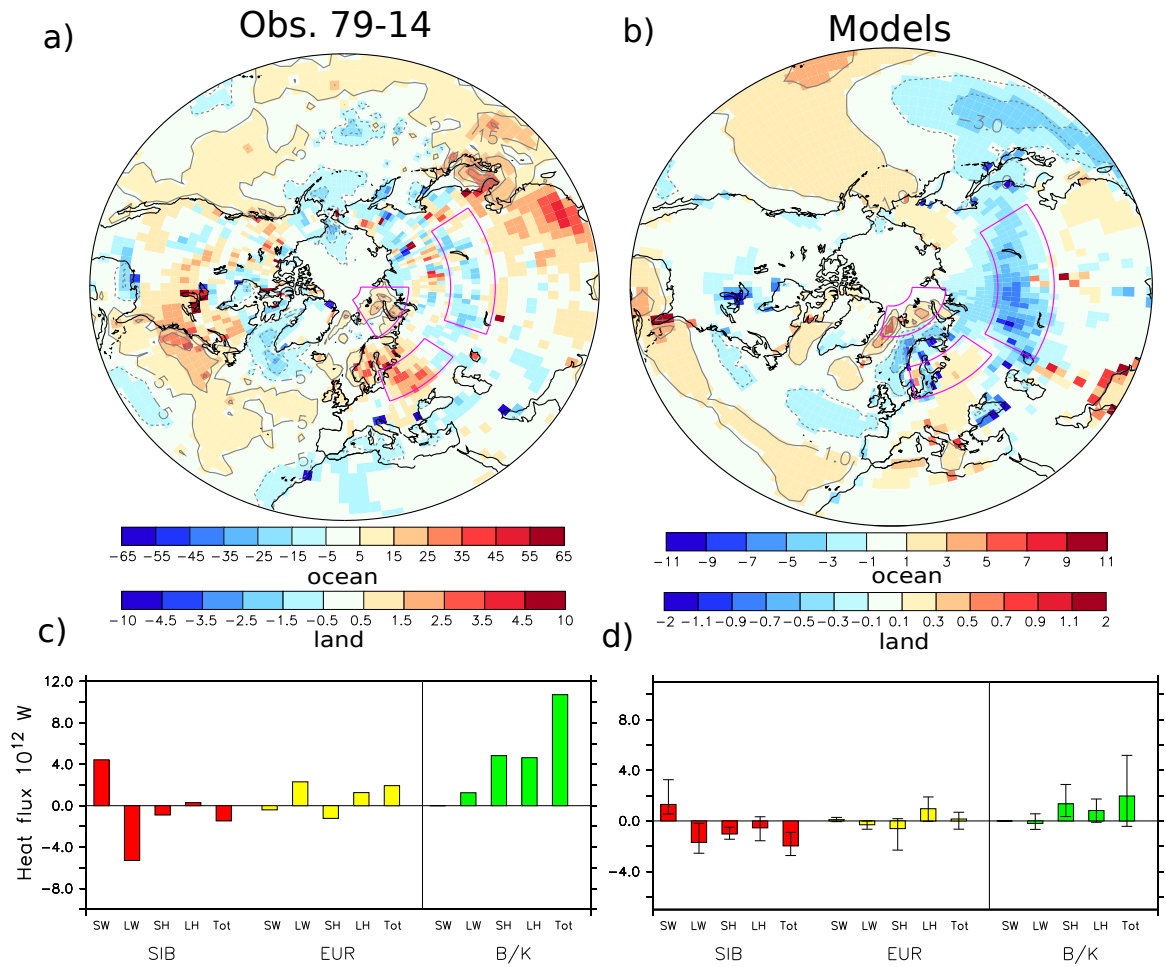

Fig. 9 : November heat flux thermodynamical component, positive upward, in  $\text{W m}^{-2}$ , associated with the November MCA-snow index in (a) ERA-Interim and (b) the four models. The color scale is different over land and ocean to emphasize the changes over continental surfaces. Note the different contour intervals for ERA-Interim and models. (c,d) Regressions of the shortwave (SW), longwave (LW), sensible (SH), latent (LH) and total (Tot) heat flux over the Siberia (SIB), Europe (EUR) and Barents-Kara Sea (B/K) integrated over boxes shown in (a) and (b) with histograms for (c) ERA-Interim and (d) the four models mean. In (d) the error bars indicate the minimum and maximum values among models.

Fig. 10 : Regression of the SLP, in hPa (contour interval 0.5 hPa), onto the MCA-snow index, (left column) ERA-Interim and (right column) models, in (a), (b) October; (c), (d) November; (e), (f) December and (g), (h) January . The thick black line indicates 5% significance for observations or anomalies of the same sign among the four models. The contour interval at -0.2 and 0.2 hPa was added for models.

Fig. 11 : Regression of the zonal-mean temperature (gray contours and color shading, in K) and geopotential height (blue contours, in m) onto the MCA-snow normalized index, for (left column) ERA-Interim and (right column) models, in (a), (b) November; (c), (d) December and (e), (f) January. Colors indicate zonal mean temperature (left) level of significance below 10% or (right) anomalies of the same sign among the four models.

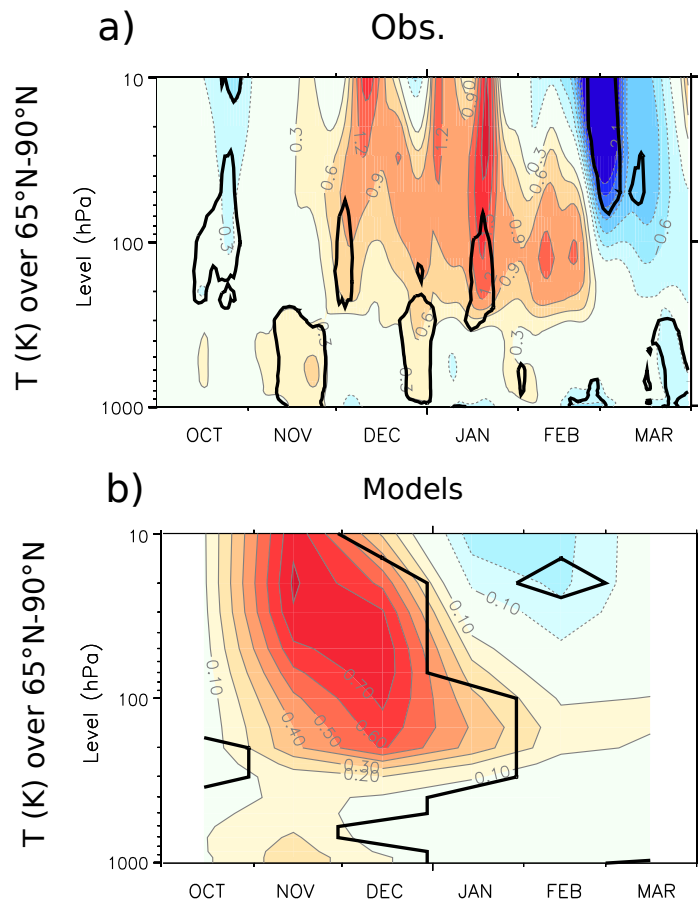

Fig. 12 : Regression of the temperature over the polar cap (65°N-90°N) onto the MCA-snow normalized index, for (a) ERA-Interim and (b) models. The thick black lines indicate (a) level of significance below 10% or (b) anomalies of the same sign among the four models. Note the different contour intervals in (a) and (b).

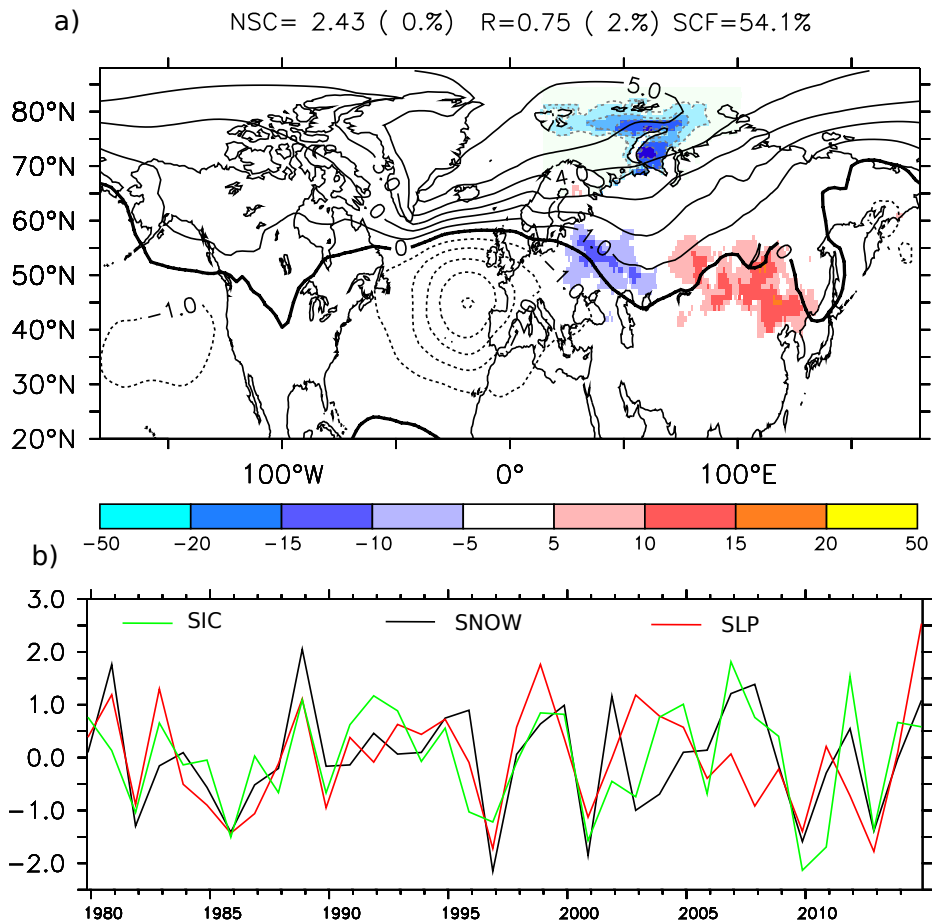

Fig. 13 : (a) Snow cover (color over land, in %) and SIC (color over ocean, in %) homogeneous covariance map and SLP (in hPa) heterogeneous map for the first MCA mode using combined snow/sea-ice in November and SLP in December for ERA-Interim. (b) (black) MCAcat\_SCE, (red) MCAcat\_SIC and (green) atmospheric SLP yearly time series from the MCA (normalized).

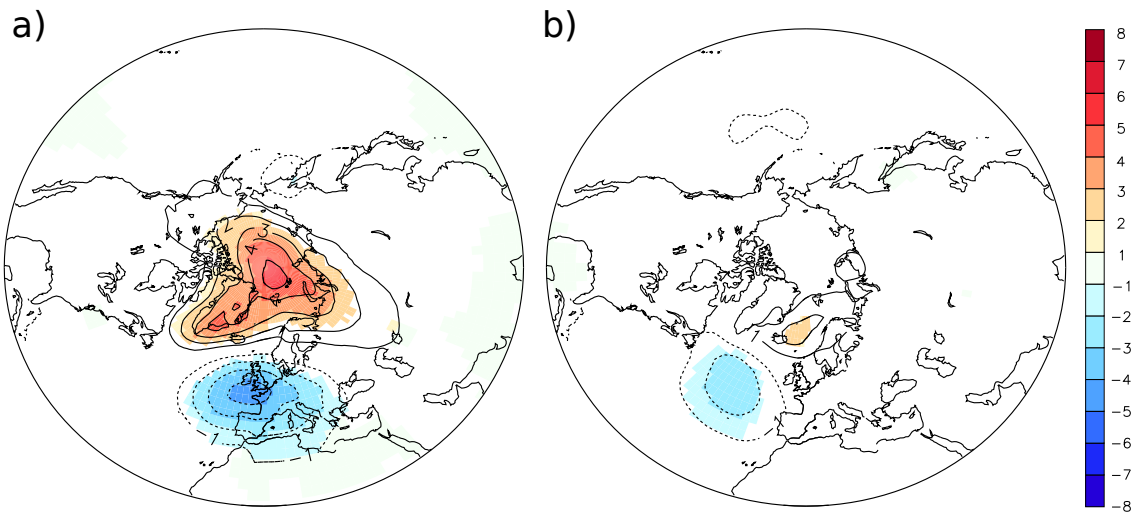

Fig. 14: Regression slopes of a bivariate regression of the December SLP (in hPa) for the (a) MCA-snow, and (b) MCA-SIC indices. Colors indicate level of significance below 10%.

Fig. 15 : Regression slopes of a multivariate regression of the SLP (in hPa) onto the (a) snow dipole, (b) Barents-Kara Sea SIC and (c) SCA indices. In (a-c) colors indicate level of significance below 10%. (d) R<sup>2</sup> value of univariate regressions using the AO index as predictand and snow dipole, Barents-Kara Sea SIC or SCA as predictor. ALL indicates the R<sup>2</sup> when using the three indices in a multivariate regression. Note that the y-axis is different for observation (bars, left axis) and models (symbols, right axis). The black symbols (bars) provide the results for models (observations), thick symbols (bars) indicating level of significance of R<sup>2</sup> below 10%.

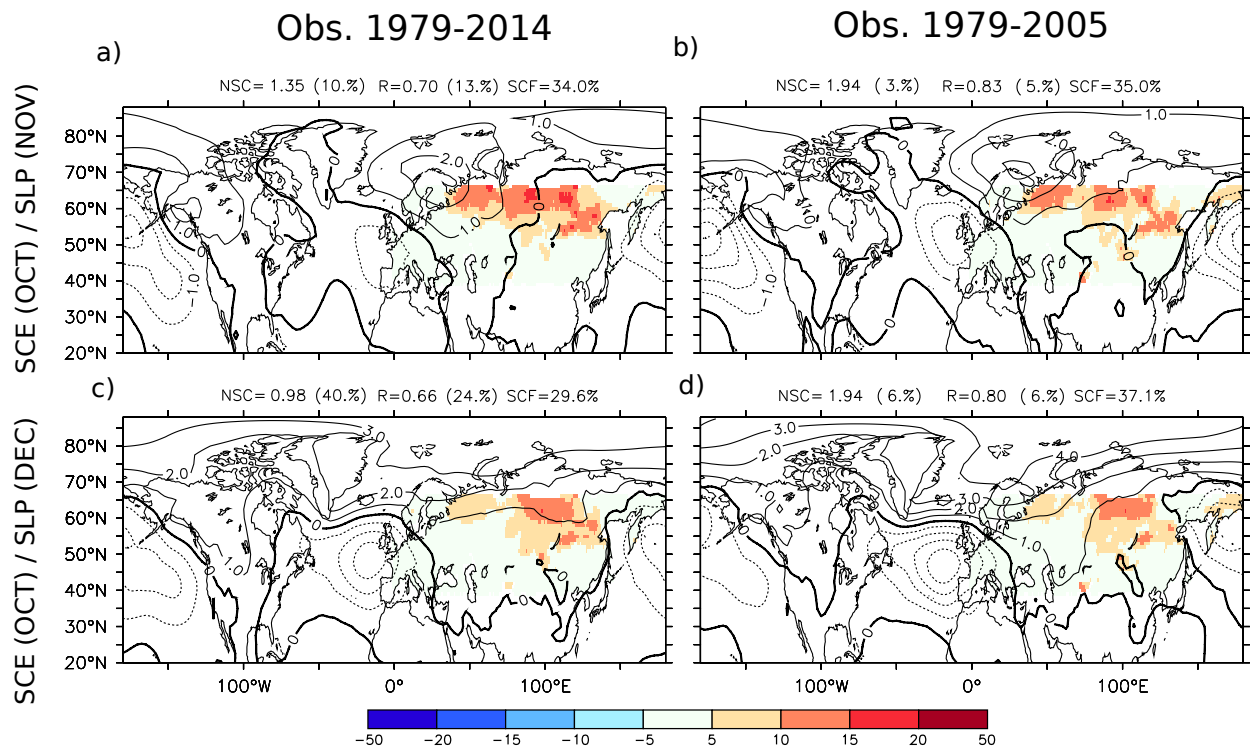

Fig. A1 : (a) Homogeneous October snow cover fraction (in %) and November heterogeneous SLP (in hPa) covariance maps for the first MCA mode, when the snow cover leads by one month the atmosphere, for ERA-Interim during 1979-2014. (b) Same as (a) but for the 1979-2005 period. (c) Same as (a) but using the December SLP. (d) Same as (c) but for the 1979-2005 period.
