Abstract

Systems describing the dynamics of proliferative and quiescent cells are commonly used as computational models, for instance for tumor growth and hematopoiesis. Focusing on the very earliest stages of hematopoiesis, stem cells and early progenitors, we introduce a new method, based on an energy/Lyapunov functional to analyze the long time behavior of solutions. Compared to existing works, our method has the advantage that it can be extended to more complex situations. We treat a systems with space variable and diffusion, then we adapt the energy functional to models with three equations.

Introduction

Systems describing the dynamics of proliferative and quiescent cells are commonly used as computational models, for instance for tumor growth and hematopoiesis [4, 10, 14, 15, 16, 23]. The typical dynamical system, introduced in the papers of Gyllenberg and Webb [13], describes the populations $n_P(t) \geq 0$ (proliferative cells) and $n_Q(t) \geq 0$ (quiescent cells) with a control by the total population $n(t)$, as

$$\left\{ \begin{array}{ll} \frac{d}{dt}n_P(t) &= [\beta - s_+(n(t))]n_P(t) + s_-(n(t))n_Q(t), & n_P(t=0) = n_P^0 > 0, \\ \frac{d}{dt}n_Q(t) &= s_+(n(t))n_P(t) - (s_-(n(t)) + \delta)n_Q(t), & n_Q(t=0) = n_Q^0 > 0, \\ n(t) &:= n_P(t) + n_Q(t). \end{array} \right. \quad (1)$$

Here, $\beta > 0$ represents the cumulated proliferation rate of proliferative cells, $\delta > 0$ represents the death rate of quiescent cells, the smooth function $s_+ > 0$, $s_- \geq 0$ define controls of the system. The

[†]Sorbonne Univ., UPMC Univ. Paris 06, Laboratoire Jacques-Louis Lions UMR CNRS 7598, Univ. Paris-Diderot, F75005 Paris

authors in [13] show the nonlinear stability of the non-zero steady state using the Poincaré-Bendixson theorem.

Our purpose is to introduce another argument, based on an energy functional, or Lyapunov functional in the language of dynamical systems, which leads to an analytical method that can be extended to more elaborated models. We have in mind two extensions.

Firstly, we consider Partial Differential Systems which take into account spatial extension and random motion of cells. Consider a smooth and bounded region Ω of $\mathbb{R}^d$, the simplest system is

$$\begin{cases} \frac{\partial}{\partial t} n_P(t) = [\beta - s_+(n(t))] n_P(t) + s_-(n(t)) n_Q(t) + \Delta n_P, & x \in \Omega, t > 0, \\ \frac{\partial}{\partial t} n_Q(t) = s_+(n(t)) n_P(t) - (s_-(n(t)) + \delta) n_Q(t) + \Delta n_Q, \\ n(x, t) := n_P(x, t) + n_Q(x, t), \\ \frac{\partial}{\partial \nu} n_P = \frac{\partial}{\partial \nu} n_Q = 0, & x \in \partial\Omega, \end{cases}$$

with smooth initial data $n^P(x) > 0$, $n_Q^0(x) > 0$. Again our purpose is to study the long term convergence in this case, using our energy functional.

Secondly, we have in mind to introduce more complex biological content. This is the case in hematopoiesis where the dynamic (1) represents a two stage stem cell population. We may add a third compartment which corresponds to the early progenitor cells encountered in hematopoiesis, and written as

Figure 1: Diagram of the three compartmental model (2).

$$\begin{cases} \frac{d}{dt} n_P(t) = [\beta - s_+(n(t))] n_P(t) + s_-(n(t)) n_Q(t) + \eta u(t), & n_P(t=0) = n_P^0 > 0, \\ \frac{d}{dt} n_Q(t) = s_+(n(t)) n_P(t) - [s_-(n(t)) + \delta] n_Q(t), & n_Q(t=0) = n_Q^0 > 0, \\ \frac{d}{dt} u(t) = -\alpha u(t) + \epsilon n_P(t), & u(t=0) = u^0 > 0, \\ n(t) := n_P(t) + n_Q(t) \end{cases} \quad (2)$$

Here $n_P(t)$ and $n_Q(t)$ stand for a population of proliferative and quiescent stem cells, respectively, while $u(t)$ represents the corresponding population of early progenitor cells, assumed to proceed from proliferative stem cells only. Note that we allow a fraction η of progenitor cells to de-differentiate and go back to the proliferative stem cell compartment, a case that in principle occurs only in cancer (in particular leukemic) cell populations [3]. In this representation, we do not consider the

whole hematopoietic tree (as done in, e.g., [2, 24]), but only its most immature components. Indeed, having in mind, as in [2, 24], future applications to acute myeloid leukemia, that emerges from these early stages [17], we believe that this is the right place in the hematopoietic tree to set the relevant mathematical model and its analysis.

The rest of the paper is organized as follows. In the first section, we introduce the assumptions and the energy method and we use it for the system (1) in order to prove its global, nonlinear asymptotic stability. In section §2, we analyze the PDE system (16) and show that the energy functional can be used to prove again the long time convergence to the homogeneous steady state. The last section is devoted to the construction of a variant of the energy functional adapted to the three-compartment system (2).

1 Assumptions and the energy method

1.1 Assumptions and converge to the non-zero steady state

Following [13], we consider that the parameters satisfy

Assumption for the existence of a unique non-zero steady state

$$s'_+(\cdot) \geq 0, \quad s'_-(\cdot) \leq 0, \quad s_+(\infty) = \lim_{n \rightarrow \infty} s_{\pm}(n) < \infty, \quad (3)$$

$$s'_+(n) - s'_-(n) > 0, \quad \forall n \geq 0, \quad \delta s_+(0) < \beta(\delta + s_-(0)), \quad \beta(\delta + s_-(\infty)) < \delta s_+(\infty), \quad (4)$$

Assumption for global stability

$$\beta < s_-(n) + s_+(n) + \delta, \quad \forall n \geq 0. \quad (5)$$

With the assumptions (3), (4), it is well established [13] that there is a unique non-zero steady state of system (1) which is characterized by

$$\delta s_+(n_{\infty}) = \beta(\delta + s_-(n_{\infty})), \quad n_{P,\infty} = \frac{\delta}{\beta + \delta} n_{\infty}, \quad n_{Q,\infty} = \frac{\beta}{\beta + \delta} n_{\infty}. \quad (6)$$

Additionally, with the assumption (5), these authors prove that, as $t \rightarrow \infty$,

$$n(t) \rightarrow n_{\infty}, \quad n_P(t) \rightarrow n_{P,\infty}, \quad n_Q(t) \rightarrow n_{Q,\infty}. \quad (7)$$

1.2 The energy method

For convenience, we change the variables and the time of the system to

$$g(t) = \frac{n_P(t)}{n(t)} \in (0, 1), \quad \Sigma_{\pm}(n) = \frac{s_{\pm}(n)}{\beta + \delta}, \quad \tau = (\beta + \delta)t. \quad (8)$$

Nonetheless, in what follows we still note the time by t . In these new variables, the system reads

$$\begin{cases} \frac{d}{dt}g(t) = F(g(t), n(t)), \\ \frac{d}{dt}n(t) = n(t)(g(t) - g_{\infty}), \quad g_{\infty} = \frac{\delta}{\beta + \delta}, \\ 0 < g(0) = g^0 < 1, \quad 0 < n(0) = n^0 < \infty. \end{cases} \quad (9)$$

The nonlinearity is defined as $F(g, n) = -g^2 + g[1 - \Sigma_+(n) - \Sigma_-(n)] + \Sigma_-(n)$, which we also write as

$$\begin{cases} F(g, n) = -(g - g_\infty)^2 - a(n)(g - g_\infty) + b(n), \\ a(n) = \Sigma_+(n) + \Sigma_-(n) + 2g_\infty - 1, \quad b(n) = F(g_\infty, n). \end{cases} \quad (10)$$

With these notations and the assumptions (3)–(5), we obtain that $a(\cdot)$, $b(\cdot)$ are smooth and bounded functions. The properties of $a(\cdot)$, $b(\cdot)$, and the definition of the steady state n_∞ , can be written as

$$b(0) = F(g_\infty, 0) > 0, \quad b(\infty) = F(g_\infty, \infty) < 0, \quad b(n_\infty) = F(g_\infty, n_\infty) = 0, \quad (11)$$

$$a(n) > 0, \quad b'(n) < 0, \quad \forall n \geq 0. \quad (12)$$

We introduce the energy of the system

$$E(t) = \frac{1}{2}n(t)^2(g - g_\infty)^2 + G(n(t)) \quad (13)$$

with, using assumption (11),

$$G(n) = - \int_{n_\infty}^n mF(g_\infty, m) dm = - \int_{n_\infty}^n mb(m)dm \xrightarrow{n \rightarrow \infty} \infty. \quad (14)$$

Lemma 1.1 *With the assumptions (11), (12), the energy $E(t)$ defined by (13) is decreasing and, for $(g^0, n^0) \neq (g_\infty, n_\infty)$, we have*

$$\frac{d}{dt}E(t) = -n(t)^2(g(t) - g_\infty)^2 a(n(t)) < 0. \quad (15)$$

Proof. We compute

$$\begin{aligned} \frac{d}{dt}E(t) &= n(t)^2(g(t) - g_\infty)^3 + n(t)^2(g(t) - g_\infty) [F(g(t), n(t)) - F(g_\infty, n(t))] \\ &= n(t)^2(g(t) - g_\infty)^2(1 - \Sigma_0(n(t)) - \Sigma_1(n(t)) - 2g_\infty), \end{aligned}$$

and we conclude using the definition of $a(\cdot)$ in (10). $\square$

1.3 The convergence theorem

We are now ready for our version of the convergence result in [13],

Theorem 1.2 *With the assumptions (11), (12), the solutions of (9) are bounded and, as $t \rightarrow \infty$, $g(t) \rightarrow g_\infty$ and $n(t) \rightarrow n_\infty$.*

Proof. (i) Because of the energy inequality (15), we have $E(t) \leq E(0)$ and thus $G(n(t)) \leq E(0)$. We conclude that $n(t)$ is bounded using (14).

(ii) Because n and g are bounded, the equation (9) shows that n and g are Lipschitz continuous. Therefore, $n(\cdot)^2(g(\cdot) - g_\infty)^2$ is also bounded and Lipschitz continuous. Since from the energy dissipation we have

$$\int_0^\infty n(t)^2(g(t) - g_\infty)^2 a(n(t)) dt \leq E^0,$$

we conclude that, as $t \rightarrow \infty$, we have

$$n(t)^2(g(t) - g_\infty)^2 a(n(t)) \rightarrow 0.$$

Because of assumption (12), this implies that

$$n(t)^2(g(t) - g_\infty)^2 \rightarrow 0.$$

(iii) Because the energy decays, it has a limit E_∞ . Combined with the above information, we conclude that, as $t \rightarrow \infty$, we have

$$G(n(t)) \rightarrow E_\infty,$$

and by continuity $n(t)$ has a limit $\bar{n}_\infty$.

(iv) Arguing by contradiction, we assume that $\bar{n}_\infty = 0$. Then, for t large enough, the dynamics of $g(t)$ resembles the solution of the Riccati equation

$$\frac{d}{dt}g(t) = F(g(t), 0) = -(g(t) - g_\infty)^2 + a(0)(g(t) - g_\infty) + b(0).$$

As $t \rightarrow \infty$, the solution $g(t)$ of this equation tends to $\bar{g}_\infty = g_\infty + \frac{1}{2}[-a(0) + \sqrt{a(0)^2 + 4b(0)}] > g_\infty$. This last inequality holds thanks to the assumptions (11), (12). But inserting this information in the equation for $n(t)$ shows that $n(t) \rightarrow \infty$ which is impossible, this is a contradiction. Therefore $\bar{n}_\infty \neq 0$.

(v) As a consequence, from step (ii) we deduce that $g(t) \rightarrow g_\infty$. From the equation for $g(t)$, we conclude that $b(\bar{n}_\infty) = 0$ which means that $\bar{n}_\infty = n_\infty$. $\square$

2 Model with space and diffusion

The method with the energy/Lyapunov functional presents another advantage which is a possible extension to the context where spatial distribution is also considered. An example is the case with spatial diffusion and we now consider distributions $n_P(x, t)$, $n_Q(x, t)$ with $x \in \Omega$ a smooth bounded domain of $\mathbb{R}^d$. We use the equations

$$\left\{ \begin{array}{l} \frac{\partial}{\partial t} n_P(x, t) = [\beta - s_+(n(x, t))] n_P(t) + s_-(n(x, t)) n_Q(x, t) + \Delta n_P, \quad x \in \Omega, t > 0, \\ \frac{\partial}{\partial t} n_Q(x, t) = s_+(n(x, t)) n_P(x, t) - (s_-(n(x, t)) + \delta) n_Q(x, t) + \Delta n_Q, \\ n(x, t) = n_P(x, t) + n_Q(x, t), \\ \frac{\partial}{\partial \nu} n_P = \frac{\partial}{\partial \nu} n_Q = 0, \quad x \in \partial\Omega. \end{array} \right. \quad (16)$$

This system is completed with smooth initial data $n_P^0(x) > 0$, $n_Q^0(x) > 0$. It is of semi-linear type and global existence is granted because the nonlinearity is Lipschitzian, and solutions are smooth and positive, see [6, 11, 20, 22]. Solutions are only locally bounded with possibly exponential growth.

In order to adapt the energy functional $E(t)$ defined by (13) to the case at hand, we need to go back to the unknowns n_P , n_Q and use

$$\mathcal{E}(n_P, n_Q) = \frac{1}{2}(n_P + n_Q)^2 \left(\frac{n_P}{n_P + n_Q} - g_\infty \right)^2 + G(n_P + n_Q)$$

We now define the total energy with

$$E(t) = \int_{\Omega} \mathcal{E}(n_P(x, t), n_Q(x, t)) dx.$$

We may now state our result for the system with space, it is of global nature but with a restriction on the initial data which is limited by the convexity region of the energy $\mathcal{E}$.

Theorem 2.1 *We make the assumptions (3)–(5) and that $\max_x \mathcal{E}(n_P^0(x), n_Q^0(x))$ is small enough (less than n_{∞} is enough). Then, there is a smooth solution to the semi-linear parabolic system (16) and it satisfies $n(x, t) \leq n_M^0$, the total energy $E(t)$ decays and, as $t \rightarrow \infty$,*

$$n(x, t) \rightarrow n_{\infty}, \quad g(x, t) \rightarrow g_{\infty}, \quad \text{in } L^2(\Omega).$$

The end of the section is devoted to prove this theorem.

2.1 Convexity of $\mathcal{E}$

To begin with, we need to study the convexity properties of $\mathcal{E}$. For that purpose, we define a function which is essential for our study

$$f(n) = F(g_{\infty}, n) - n \frac{\partial F}{\partial n}(g_{\infty}, n) = b(n) - nb'(n).$$

We may calculate the Hessian of $\mathcal{E}$

$$\text{Hess}(\mathcal{E}) = \begin{pmatrix} (1 - g_{\infty})^2 + f(n) & -g_{\infty}(1 - g_{\infty}) + f(n) \\ -g_{\infty}(1 - g_{\infty}) + f(n) & g_{\infty}^2 + f(n) \end{pmatrix}$$

still with $n = n_P + n_Q$, $g = \frac{n_P}{n}$. We can compute

$$\text{Tr}(\text{Hess}(\mathcal{E})) = g_{\infty}^2 + (1 - g_{\infty})^2 + 2f(n),$$

$$\det(\text{Hess}(\mathcal{E})) = f(n).$$

Because convexity is equivalent to the non-negativity of these two quantities, it is reduced to those n such that $f(n) \geq 0$. Clearly this is the case for $n \leq n_{\infty}$ since $F(g_{\infty}, \cdot)$ is positive on this interval and decreasing (see assumptions (11), (12)).

However, we can see that for n large, this condition cannot be fulfilled. Indeed, $f(n) \geq 0$ means $b(n) - nb'(n) \geq 0$, which would imply that $b(n) = F(g_{\infty}, n) \rightarrow -\infty$ as $n \rightarrow \infty$ while we assume that F is bounded.

2.2 Condition on the initial data

When the Laplacian is considered, it is useful to preserve the convexity zone all along the dynamics, see e.g. [6, 11, 20, 22]. Therefore, we need a condition on the initial data which we state as follows. Consider the value n_M^0 , necessarily larger than n_{∞} , such that

$$f(n_M^0) = 0 \quad \text{and} \quad f(n) > 0 \quad \text{for } n < n_M^0. \quad (17)$$

We assume that

$$\mathcal{E}(n_P, n_Q) \leq \max_x \mathcal{E}(n_P^0(x), n_Q^0(x)) \implies n_P + n_Q \leq n_M^0. \quad (18)$$

This somehow abstract condition can be satisfied with more explicit assumptions, for instance

$$\max_x \mathcal{E}(n_P^0(x), n_Q^0(x)) \leq \min_{0 \leq g \leq 1} E(g, n_M^0).$$

This is the precise size condition needed in the statement on Theorem 2.1.

2.3 Conclusion

We may now conclude the proof of this theorem which relies on very standard tools for parabolic systems. Therefore, we just indicate the reason why assumption (17) is used. We compute the energy dissipation relation

$$\begin{aligned} \frac{\partial}{\partial t} \mathcal{E} = \Delta \mathcal{E} & - (\nabla n_P, \nabla n_Q) \cdot \text{Hess}(\mathcal{E}) \cdot (\nabla n_P, \nabla n_Q) \\ & - n(x, t)^2 (g(x, t) - g_\infty)^2 a(n(x, t)). \end{aligned}$$

Because initially we have $\text{Hess}(\mathcal{E}(t=0, x)) \leq 0$ for all $x \in \Omega$, we conclude from the maximum principle that

$$\mathcal{E}(x, t) \leq \max_x \mathcal{E}(n_P^0(x), n_Q^0(x)), \quad \forall x \in \Omega, t \geq 0.$$

Therefore the condition (18) tells us that $n(x, t) \leq n_M^0$ and the definition (17) implies that $\mathcal{E}(t, x)$ remains convex all along the dynamics. Therefore the solution satisfies

$$n(x, t) \leq n_M^0 \quad \forall x \in \Omega, t \geq 0.$$

Standard use of the energy dissipation leads to the conclusion that $(\nabla n_P(x, t), \nabla n_Q(x, t))$ belongs to $L^2(\mathbb{R}^+; \Omega)$. Time compactness follows from the Lions-Aubin Lemma, and thus the family $(\nabla n_P(x, t), \nabla n_Q(x, t))$ converges, as $t \rightarrow \infty$ to an homogeneous state for large times. Finally, the reasoning of Section 1.3 leads to the conclusion of Theorem 2.1.

3 The 3-compartment hematopoiesis system

The flexibility of the energy method for the model with proliferative and quiescent cells can also be illustrated with a 3 by 3 system. This type of model is used for describing hematopoietic stem cell dynamic and a third compartment corresponds to the early progenitor cells encountered in hematopoiesis which are denoted by $u(t)$ in this section. Hematopoiesis is a wide subject, with several mathematical faces and the interested reader can consult for instance [1, 9, 21].

3.1 The model equation

The system proposed here is the extension of (1) written

$$\begin{cases} \frac{d}{dt}n_P(t) &= [\beta - s_+(n(t))]n_P(t) + s_-(n(t))n_Q(t) + \eta \frac{n(t)}{1+n(t)}u(t), \\ \frac{d}{dt}n_Q(t) &= s_+(n(t))n_P(t) - [s_-(n(t)) + \delta]n_Q(t), \\ \frac{d}{dt}u(t) &= -\alpha \frac{n(t)^2}{(1+n(t))^2}u(t) + \frac{n(t)}{(1+n(t))^2}\epsilon n_P(t), \\ n(t) &= n_P(t) + n_Q(t), \end{cases} \quad (19)$$

where we still use the notations and assumptions of section 1. We consider that the exchanges between the proliferating hematopoietic stem cells and the early progenitor compartment are small, i.e., we are going to consider the perturbative regime

$$\epsilon\eta \ll 1.$$

We assume here that de-differentiation of the progenitor cells into hematopoietic stem cells (the passage from u to n_P measured by η) is much less important than the maturation of hematopoietic stem cells (the converse passage). De-differentiation has been observed in recent biological studies on cancers [5, 12, 25], and investigated in modelling studies by varying its rate [3, 18]. However, nothing is known for certain concerning its actual rate in different types and stages of cancers, nor whether it is cause or consequence of cancer emergence, except the fact that high de-differentiation rates seem to be related to cancer aggressiveness. The case $\eta \ll \epsilon$ is thus relevant, at least in health or in very early cancer initiation.

However a difficulty remains; the energy dissipation $-n^2a(n)(g - g_\infty)$ in (15) does not provide enough coercivity by lack of a term $n - n_\infty$. For that technical reason, we have introduced a modulation of the exchanges with the ratio $\frac{n(t)^2}{(1+n(t))^2}$ and the energy modulation has to be tuned appropriately.

We notice that solutions exists globally because positivity is preserved and the total number of cells is controlled by

$$\frac{d}{dt}[n_P(t) + n_Q(t) + u(t)] \leq (\beta + \epsilon)n_P(t) + \eta u(t) \leq \max(\beta + \epsilon, \eta)[n_P(t) + n_Q(t) + u(t)],$$

and the Gronwall lemma controls the solutions with an exponential growth in time.

We perform the same change in unknowns (equations (8)) as in section 1, set $u = \epsilon v$, and we get:

$$\begin{cases} \frac{d}{dt}g(t) &= \tilde{F}(g(t), n(t)) + \frac{\eta\epsilon}{1+n(t)}(1 - g(t))[(v(t) - \tilde{v}_\infty) - \frac{\tilde{v}_\infty}{1 + \tilde{n}_\infty}(n - \tilde{n}_\infty)], \\ \frac{d}{dt}n(t) &= n(t)(g(t) - \tilde{g}_\infty) + \eta\epsilon \frac{n(t)}{1+n(t)}(v(t) - \tilde{v}_\infty) - \eta\epsilon \frac{\tilde{v}_\infty}{1 + \tilde{n}_\infty} \frac{n(t)}{1 + n(t)}(n(t) - \tilde{n}_\infty), \\ \frac{d}{dt}v(t) &= -\alpha \frac{n(t)^2}{(1+n(t))^2}(v(t) - \tilde{v}_\infty) + \frac{n(t)^2}{(1+n(t))^2}(g(t) - \tilde{g}_\infty), \end{cases} \quad (20)$$

with the following definitions, in particular of the steady state $(\tilde{n}_\infty, \tilde{g}_\infty, \tilde{v}_\infty)$,

$$\tilde{g}_\infty = \frac{\delta}{\beta + \delta + \gamma}, \quad \gamma = \frac{\eta\epsilon}{\alpha} \cdot \frac{1}{1 + \tilde{n}_\infty}, \quad \alpha\tilde{v}_\infty = \tilde{g}_\infty.$$

$$\tilde{F}(g, n) = g[1 - \Sigma_+(n) - \Sigma_-(n)] + \Sigma_-(n) - g^2 + \eta\varepsilon \frac{\tilde{v}_\infty}{1 + \tilde{n}_\infty}(1 - g), \quad \tilde{F}(\tilde{g}_\infty, \tilde{n}_\infty) = 0.$$

As before, we can rewrite $\tilde{F}(g, n)$ as

$$\tilde{F}(g, n) = -(g - \tilde{g}_\infty)^2 - (g - \tilde{g}_\infty)\tilde{a}(n) + \tilde{b}(n), \quad \tilde{a} = \Sigma_+ + \Sigma_- + 2\tilde{g}_\infty - 1 + \eta\varepsilon \frac{\tilde{v}_\infty}{1 + \tilde{n}_\infty},$$

$$\tilde{b}(n) = \tilde{F}(\tilde{g}_\infty, n) = \tilde{g}_\infty(1 - \tilde{g}_\infty) - \tilde{g}_\infty\Sigma_+(n) + (1 - \tilde{g}_\infty)\Sigma_-(n) + \eta\varepsilon \frac{\tilde{v}_\infty}{1 + \tilde{n}_\infty}(1 - \tilde{g}_\infty)$$

and the assumptions (3)–(5) have to be reinforced so as to yield the positivity of $\tilde{a}$ and the property $\tilde{b}(0) > 0$, $\tilde{b}(\infty) < 0$, then there are a_0 and $\tilde{n}_\infty$ such that

$$\tilde{a}(n) \geq a_0 > 0, \quad \tilde{b}' < 0, \quad \tilde{b}(\tilde{n}_\infty) = 0. \quad (21)$$

We also define $G(\cdot)$ with

$$G'(n) = -n\tilde{b}(n), \quad G(\tilde{n}_\infty) = 0.$$

3.2 The energy functional and long-term convergence

We need to introduce a modulation of the energy functional $E(t)$ in order to take into account the third component. Now, we define the energy by

$$\tilde{E}(t) = \frac{1}{2}n(t)^2(g(t) - \tilde{g}_\infty)^2 + G(n(t)) + \frac{\lambda}{2}(v(t) - \tilde{v}_\infty)^2 \quad (22)$$

where the constant λ is positive and small.

Theorem 3.1 *For $\lambda > 0$ small enough compared to α , a_0 and $b(\cdot)$, and $\eta\varepsilon$ small enough, we have, for some $p \in (0, 1)$,*

$$\frac{d}{dt}\tilde{E}(t) \leq -\frac{1}{2}n^2a(n)(g - \tilde{g}_\infty)^2 - \eta\varepsilon p \frac{n^2}{(1+n)^2}(n - \tilde{n}_\infty)^2 - p\alpha \frac{n^2}{(1+n)^2}(v - \tilde{v}_\infty)^2.$$

Therefore, we have the long term convergence

$$n \rightarrow \tilde{n}_\infty, \quad g \rightarrow \tilde{g}_\infty, \quad v \rightarrow \tilde{v}_\infty.$$

In this theorem, the only new difficulty relies on the elaboration of the energy dissipation. The convergence result then follows exactly as in section 1 and we skip its proof. In the end of this section, we concentrate on the dissipation of energy.

3.3 Proof of the Theorem 3.1

We may compute

$$\begin{aligned} \frac{d}{dt}\tilde{E}(t) = & -n^2a(n)(g - g_\infty)^2 - \alpha\lambda \frac{n(t)^2}{(1+n(t))^2}(v - \tilde{v}_\infty)^2 - (n - \tilde{n}_\infty)^2A + (g - \tilde{g}_\infty)(n - \tilde{n}_\infty)B \\ & + (v - \tilde{v}_\infty)(n - \tilde{n}_\infty)C + (v - \tilde{v}_\infty)(g - \tilde{g}_\infty)D, \end{aligned} \quad (23)$$

with $A, B \dots F$ determined below.

We obtain only a control on $(n - \tilde{n}_\infty)^2$ of order $\varepsilon\eta$, which is given by

$$A = \eta\varepsilon \frac{\tilde{v}_\infty}{1 + \tilde{n}_\infty} \frac{n^2}{(1+n)^2} c(n), \quad c(n) := -(1+n) \frac{\tilde{b}(n) - \tilde{b}(\tilde{n}_\infty)}{n - \tilde{n}_\infty} \geq c_0,$$

Then, the other terms are

$$\begin{aligned} B &= -\eta\varepsilon \frac{\tilde{v}_\infty}{1 + \tilde{n}_\infty} \frac{n^2}{1+n} (1 - \tilde{g}_\infty), & C &= -\eta\varepsilon \frac{n^2}{1+n} \frac{\tilde{b}(n) - \tilde{b}(\tilde{n}_\infty)}{n - \tilde{n}_\infty}, \\ D &= \eta\varepsilon \frac{n^2}{1+n} (1 - \tilde{g}_\infty) + \lambda \frac{n^2}{(1+n)^2}. \end{aligned}$$

Then, we can estimate the terms with products rather simply. We have

$$\begin{aligned} |(g - \tilde{g}_\infty)(n - \tilde{n}_\infty)B| &\leq \eta\varepsilon \frac{\tilde{v}_\infty}{\tilde{n}_\infty} n^2 (1 - \tilde{g}_\infty) (g - \tilde{g}_\infty)^2 \\ &\quad + \eta\varepsilon \frac{\tilde{v}_\infty}{\tilde{n}_\infty} \frac{n^2}{(1+n)^2} (1 - \tilde{g}_\infty) (n - \tilde{n}_\infty)^2 \end{aligned}$$

which, for $\eta\varepsilon$ small enough compared to c_0 and a_0 , are both absorbed by negative terms coming from A and from the first negative term in the energy dissipation (23).

The next term is

$$|(v - \tilde{v}_\infty)(n - \tilde{n}_\infty)C| \leq \eta\varepsilon b_1 \frac{n^2}{(1+n)^2} [(n - \tilde{n}_\infty)^2 + (v - \tilde{v}_\infty)^2]$$

which again, for $\eta\varepsilon$ small enough compared to c_0 , α and $1/b_1$, contribution is absorbed by the negative terms. Here we have used

$$b_1 = \sup_{n \geq 0} (1+n) \left| \frac{\tilde{b}(n) - \tilde{b}(\tilde{n}_\infty)}{n - \tilde{n}_\infty} \right|.$$

The last term $(v - \tilde{v}_\infty)(g - \tilde{g}_\infty)D$, can be treated in the same way and, there, we require that λ is small enough compared to a_0 . $\square$

3.4 Simulations

We illustrate the behaviour of the $3 * 3$ system (19) with some numerical simulations. We have used the parameters

$$\alpha = 0.06, \quad \beta = 0.2, \quad \delta = 0.15, \quad \epsilon = 0.1,$$

and the functions

$$\begin{cases} \Sigma_+(n) = \frac{a * n^g}{K^g + n^g}, & \Sigma_-(n) = \frac{b}{L^h + n^h}, \\ a = 0.9, \quad g = 2, \quad K = 1000, \quad b = 0.1, h = 2, \quad L = 1000. \end{cases}$$

The Figure 2 displays the solution with three values of the de-differentiation parameter η ,

$$\eta = 0, \quad \eta = 0.01, \quad \text{and} \quad \eta = 0.05.$$

Figure 2: Numerical solution of the 3×3 system (19) with three values of the de-differentiation parameter. Left: $\eta = 0$. Center: $\eta = 0.01$. Right: $\eta = 0.05$.

4 Conclusion and perspectives

In this study, we have considered a new method, of the energy/Lyapunov type, to analyze the asymptotic behavior of a stem/progenitor cell population model representing the very early stages of cell lineage maturation in health and cancer. Knowing the very low level of division in stem cells (as low as once a year for hematopoietic stem cells, as measured in [7, 8]), it has appeared relevant since the studies of Gyllenberg and Webb [13] (and earlier, of Mackey and followers [19], using age-structured models) to represent the stem cell population as compartmentalized between proliferative (cells that are engaged in the division cycle) and quiescent cells (those that are not). We have adapted this point of view here as well, with the adjunction of another maturation state, early progenitor cells, for which, for the sake of simplicity, we do not distinguish between proliferative and quiescent states.

Taking advantage of recent biological observations [5, 12, 25], we have introduced the possibility of de-differentiation from this early progenitor state to stem cell state. As briefly sketched in the text, not much is known about the actual rate of de-differentiation in health and disease, except that it has been observed at high levels in aggressive cancers. We have assumed in our proofs low levels of this rate, meaning that its rigorous relevance may be limited to health settings or initiating cancers. Nevertheless, numerical studies in other modelling contexts [3, 18] have shown that increasing its level increases the severity of the cancer at stake, and its evolution towards insensitivity to therapy, i.e., drug resistance.

Last but not least, the method we have developed in this analytical study, of the energy/Lyapunov type, allowed us to extend previous studies, initiated by Gyllenberg and Webb [13], who took advantage of the Poincaré-Bendixson theorem for plane analysis, to higher-dimensional analysis on the one hand, and to a 2-dimensional spatial model with diffusion on the other hand. We believe that both these extensions open new directions of research in the study of proliferative-quiescent cell population models.

Acknowledgments. The authors gratefully acknowledge the expert contribution to this work of François Delhommeau and Pierre Hirsch by frequent and long tutorial discussions they led with us about normal human hematopoiesis and early leukemogenesis in the department of hematology at Hospital St Antoine in Paris.

BP has received funding from the European Research Council (ERC) under the European Union's Horizon 2020 research and innovation programme (grant agreement No 740623).
