ABSTRACT

Dissomphalus schubnelli sp. nov., first fossil of the extant pristocerine genus *Dissomphalus*, is described from the Earliest Eocene amber of Oise (France). This genus comprises 424 extant species distributed worldwide (except Antarctica). *Dissomphalus schubnelli* is the third described Pristocerinae from Oise amber, showing that this subfamily was probably already very diverse at that time.

RÉSUMÉ

Dissomphalus schubnelli sp. nov., premier fossile du genre actuel *Dissomphalus* de la sous-famille Pristocerinae, est décrit dans l'ambre de l'Éocène basal de l'Oise (France). Ce genre comprend 424 espèces actuelles réparties dans le monde entier (sauf l'Antarctique). *Dissomphalus schubnelli* est le troisième Pristocerinae décrit de l'ambre de l'Oise, ce qui montre que cette sous-famille était probablement déjà très diversifiée à cette époque.

INTRODUCTION

Bethylidae are frequently found in Cenozoic amber (Azevedo *et al.* 2018), especially in the earliest Eocene Oise amber of France. We have already recorded one Bethylinae (*Eupsenella eocenica* De Ploëg & Nel, 2004), three Epyrinae (*Elektroepyris magnificus* Perrichot & Nel, 2008, *Chlorepyparis gallicus* (Perrichot & Nel, 2008), and *Epyris moulyi* Falières & Nel, 2018), one Scleroderminae *Paleoscleroderma lamarrei* Falières & Nel, 2019, two Pristocerinae (*Pristocera alaini* Falières and Nel, 2019, *Eopristocera bilobata* Falières & Nel, 2019), and one Protopristocerinae (De Ploëg & Nel 2004; Perrichot & Nel, 2008; Falières & Nel 2019, in press, submitted). Thus this hymenopteran family of parasitoids was already well established and diverse in the Paleogene. Here we describe the first representative in this amber of the pristocerine extant genus *Dissomphalus* Ashmead, 1893.

MATERIAL AND METHODS

The fossil was embedded in a small clear piece of amber. It has been prepared using a diamond disk, examined using a Nikon binocular microscope SMZ 1500. Photographs have been taken with an Amscope camera MU900, and the images treated with Adobe Photoshop Element 12.

The nomenclature and classification follow Terayama (2006) and Azevedo *et al.* (2018).

Main measurements and indices used are as follow: length of forewing (LFW); length of head (LH); width of head (WH); width of frons (WF); height of eye (HE); ocello-ocular line (OOL); width of ocellar triangle (WOT); diameter of anterior ocellus (DAO); vertex-ocular line (VOL).

The nomenclature of integument sculpture follows Harris (1979).

SYSTEMATIC PALEONTOLOGY

Class INSECTA Linnaeus, 1758

Order HYMENOPTERA Linnaeus, 1758

Family BETHYLIDAE Haliday, 1840

Subfamily PRISTOCERINAE Mocsáry, 1881

Genus *Dissomphalus* Ashmead, 1893

Dissomphalus schubnelli sp. nov.

(Figs 1-5)

HOLOTYPE. MNHN.F.A71308 (PA 16948), male, stored in the collections of the Muséum National d'Histoire Naturelle, Paris, France.

TYPE STRATA. Lowermost Eocene, Sparnacian, level MP7 of the mammal fauna of Dormaal.

TYPE LOCALITY. Le Quesnoy, Chevrière, region of Creil, Oise department, France.

ETYMOLOGY. Named after the entomologist Mr. Thomas Schubnell, student of the second author.

DIAGNOSIS. Hypopygium posteriorly triangular, outer median surface flat; clypeus wholly prominent forward, median lobe not well-outlined; dorsal pronotal area short; notauli well-developed and complete; metasomal tergum II longer than I; metasomal tergum II without posterolateral margin strongly incurved; tergal process with pair of dark round pits; no tergal process on tergum III; vein Rs&M of forewing rather oblique.

DESCRIPTION. Male; body 1.25 mm long, not depressed, not strongly foveolate; LFW 0.98 mm; head and mesosoma black; metasoma castaneous lightly iridescent, legs castaneous, antenna castaneous; wings hyaline.

Head smooth, not roughly sculptured; mandible with five apical teeth; five maxillary palpomeres, two or three hardly visible labial palpomeres; no spine on gena; clypeus wholly prominent forward, median lobe not well-outlined; antenna rather long, reaching mid part of metapectal-propodeal complex; 11 flagellomeres, cylindrical but basally narrowed; scape: 0.08 mm long x 0.04 mm wide, pedicel: 0.05 x 0.03 mm, F1: 0.05 x 0.03 mm, F2: 0.06 x 0.03 mm, F3: 0.06 x 0.04 mm, F4: 0.07 x 0.03 mm, F5: 0.05 x 0.04 mm, F6: 0.06 x 0.04 mm, F7: 0.05 x 0.04 mm, F8: 0.05 x 0.04 mm, F9: 0.05 x 0.04 mm, F10: 0.04 x 0.04 mm, F11: 0.08 x 0.04 mm; frons with numerous setae; dorsal part occipital carina present; eye glabrous; WH 0.28 mm; LH 0.34 mm; OOL 0.14; ocellar triangle equilateral.

Mesosoma: dorsum smooth, not roughly sculptured but punctured; pronotum with anterior margin of disc apparently not carinate; dorsal pronotal area short; notauli well-developed and complete; parapsidal signum absent or strongly reduced; mesoscuto-mesoscutellar suture opened in its median part, with two lateral foveae, each linked to the suture by thin line; metanotum with medium region narrower than lateral regions, developed medially and overlapping mesoscutellum posteriorly; metanotal groove without foveae but with setae; metapectal-propodeal complex smooth with posterior carina and very small postero-lateral spines.

Forewing covered with microtricha and bordered with small setae; anterior border not angularly incurved anterior to pterostigma; costal vein present; vein 2r-rs&Rs vein long and as strong as other veins but not closing cell 2R1; strong vein cu-a more distal and vein M; a vein Cu and a vein A distal to cu-a; cells R, 1Cu, 2Cu closed; cells 1R1 and 1M absent; no basal stub of Rs+M; poststigmal abscissa of R1 very short, ghost FRR (first recurrent vein) and SMC cell (submarginal cell) present.

Metasoma: short petiole; seven tergites, convex, partly covering sternites; posterolateral margin of tergite II without posterolateral margin strongly incurved, with pair of lateral pits; tergite III without tergal process; hypopygium entire, posteriorly triangular.

Length of tergites: T1 about 0.05 mm, T2 0.12 mm, T3 0.07 mm, T4 0.08 mm, T5 0.07 mm, T6 0.06 mm, T7 0.05 mm.

DISCUSSION

Following the key to subfamilies of Azevedo *et al.* (2018), *Dissomphalus schubnelli* sp. nov. falls in Pristocerinae because of the following characters: male fully winged; forewing with Rs+M vein absent; metanotum developed medially and overlapping mesoscutellum posteriorly. After the key to pristocerine genera, it would fall near the genus *Dissomphalus* because of the body size smaller than 15 mm; hypopygium not deeply divided into two lobes, posterior margin not incurved, with outer median surface flat; clypeus wholly prominent forward, with median lobe not well-outlined; dorsal pronotal area short; notauli well-developed and complete; metasomal tergum II longer than I; metasomal tergum II without posterolateral margin strongly incurved; with tergal process as a pair of dark round pits; no tergal process on tergum III. Benoit (1956), Terayama (1996) and Azevedo (2014) revised the genus *Trichiscus* Benoit, 1956, closely related to *Dissomphalus*, indicating that the former has tergal processes in the metasomal segment III, consisting of some paralleled rows of setae placed on anterior third of

lateral surface. These structures are clearly absent in *Dissomphalus schubnelli*. Thus we tentatively attribute this fossil to the genus *Dissomphalus*.

At least the Thai, African, and Neotropical species of *Dissomphalus* have a small median concavity on the hypopygium, unlike *Dissomphalus schubnelli* (Azevedo 1999, 2003, 2010; Mugrabi & Azevedo 2013). Nevertheless it was not possible to compare *Dissomphalus schubnelli* with the extant species because the necessary male genitalia were not visible. *Dissomphalus schubnelli* is likely to be a new species because of its antiquity (53 Myrs old), while no extant insect is known to have lived more than 10 Myrs. The vein Rs&M of the forewing is not so vertical in *Dissomphalus schubnelli* as usual for the extant *Dissomphalus* spp. (Azevedo et al., 2018: fig. 27F), which could be a significant difference with the extant representatives of the genus. Unfortunately, this structure is generally not figured even in the most recent papers.

CONCLUSION

Dissomphalus schubnelli is the first fossil record of this genus and the third Pristocerinae from the Oise amber, suggesting that this subfamily was already very diverse during the earliest Eocene. *Dissomphalus* is a very large genus, distributed over all the continents. There is very few information on the biology of the *Dissomphalus*, Azevedo et al. (2018) indicated that some species have been recorded on Bruchidae (Coleoptera), Micromalthidae (Coleoptera) and Cecidomyiidae (Diptera). A Micromalthidae and several Cecidomyiidae are described from the Oise amber (Nel & Prokop 2006; Kirejtshuk et al. 2010), both families potential hosts for *Dissomphalus schubnelli*.

Acknowledgements

We thank two anonymous referees for their useful comments on the first version of this paper.

We thank the Lafarge-Granulat company for help with the fossil sampling and the Langlois-Meurinne family for the authorization of working on their property.
