#### Abstract

We report short and efficient syntheses of polyfunctionalized 5,8-dihydro-7H-pyrano[4,3-b]pyridin-7-ones and 1,4-dihydro-3H-pyrano[4,3-c]pyridin-3-ones which can be considered as new aza analogs of 3-isochromanones and as promising scaffolds for medicinal chemistry. Depending on the nature of the substituent, three different and complementary synthetic methodologies were used allowing the introduction of significant diversity in the substituent on the lactone ring of the pyranopyridinones. The selective $\alpha$-arylation of nitrile ( $S_{N} A r$ ) and tert-butylester enolate (Pd catalyzed) followed by an acidic mediated lactonisation gives access to original C8-functionalized pyrano[4,3-b] pyridin-7-ones and a seleno-mediated cyclization to C1 functionalized pyrano[4,3-c]pyridin-3-ones. We have also applied the outlined synthetic methodologies to the preparation of potentia semi-rigid analogs of antihistamines.

## Introduction

3-isochromanones and derivatives belong to an importan class of heterocycle compounds found in several natural products or as useful building blocks to access biological active compounds. ${ }^{[1]}$ Among them, aza analogs of 3-isochromanones or pyranopyridin ones derivatives containing a pyridine ring instead of a phenyl ring are less known heterocycles despite some promising results obtained as medicinal compounds (Figure 1). ${ }^{[2]}$ Efforts have been dedicated to the development of efficient syntheses of 3 isochromanones. ${ }^{[3]}$ However, limited synthetic procedures for the preparation of aza 3-isochromanones analogs are reported. ${ }^{[4]}$ The main synthetic approaches to the construction of the delta lactone ring of 3-isochromanones are based on sigmatropic rearrangement on benzocyclobutenes, on ynamide or Baeyer Villiger oxidation on benzocyclopentanones. ${ }^{[3 b d k]}$ These approaches are hardly appropriate to the preparation of pyranopyridinones because pyridine based starting material required in these strategies are not as accessible as their benzo analogs.

Among the four possible isomers of pyranopyridinones, three of them, namely PP1 (N1) ${ }^{[4 a b c]}$, PP3 (N3) ${ }^{[4 d e]}$ and PP4 (N4) ${ }^{[4]]}$, have been described in the literature, albeit with a narrow range of substituent (Scheme 1). However, the employed strategies narrow the introduction of structural diversity on the lactone ring, a major drawback for potential use in medicinal chemistry. Finally, the lack of effective strategies to access these useful polyfunctionalized lactones makes them still under-explored.

Herein, we present a significant improvement in the synthesis of pyranopyridinones using three different but complementary synthetic methodologies allowing for the first time to easily access polyfunctionalized 5,8-dihydro-7H-Pyrano[4,3-b]pyridin-7-ones PP1 and in particular 1,4-dihydro-3H-Pyrano[4,3-c]pyridin-3-ones PP2 for which no synthesis has been reported yet. We report an optimized synthetic procedure for selective monoarylation-nucleophilic substitution of tert-butylester enolate and $\alpha$-arylation of various het(aryl)acetonitriles with ortho-substituted chloropyridine followed by acidic mediated lactonisation. We described also an original seleno-mediated cyclization on pyridyl substituted alkynol allowing to construct substituted pyridine fused delta-lactones with efficiency. In the second part of this article, we describe the preparation of original potential semi-rigid analogs of antihistamines using the outlined synthetic methodologies.

## Results and Discussion

Unsubstituted PP1 was first synthesized in 1957 by Bohlmann and coll. from ethyl-2-methyl-pyridine-3-carboxylic acid in two steps via a cyclocondensation of dilithiated intermediate. ${ }^{[4 a]}$ Then, in 1991, Alm and coll. reported the synthesis of a polyhydroxylated pyridolactone using a $[2+2+2]$ cobalto-catalyzed cycloaddition in $9 \%$ global yield with no functionalization of the lactone ring. ${ }^{[46]}$ Our first approach to functionalized pyranopyridinone PP1 takes advantage of a Buchwald type pallado-catalyzed $\alpha$-arylation of tert-butyl acetate ester with a TBS protected chloropyridine (method A, Scheme 1). ${ }^{[5 a]}$ We prepared the required trimethylsilyl protected (2-chloropyridin-3-yl)- methanol 3 from commercially available 2-chloropyridine-3carboxaldehyde 1 by reduction with sodium borohydride followed by hydroxyl group protection with tert-butyltrimethylsilyl chloride (Scheme 2). ${ }^{[6]}$

Scheme 1. Main synthetic strategies for pyranopyridinones and our approaches

The selective monoarylation reaction of tert-butyl acetate with 3 was achieved with tert-BuXphosPdCl ( $1 \mathrm{~mol} \%$ ) as a pre-catalyst and LiHMDS as a base in toluene. The reaction was run at $0^{\circ} \mathrm{C}$ to prevent the potential formation of bis-arylated by-product. The reaction reached $86 \%$ conversion by adding $2 \mathrm{~mol} \%$ of the precatalyst. In our preliminary studies when ethyl acetate was employed instead of tert-butyl acetate, less than $30 \%$ conversion was observed However, under these conditions the same $\alpha$-arylation using substituted esters was not productive. The presence of an $\alpha$ substituent on the enolate generally leads to the instability of alkali ester enolates or the formation of bis-arylated products. ${ }^{[56]}$ The use of substituted zinc enolate esters could be required. Besides, such arylation reactions are subsequently substrate-dependent and limited to a small range of substrate. ${ }^{[7]}$ We introduce various substituent such as alkyl/ benzylic/ allylic and propargyl groups on pyrido ester 4 by a deprotonation/ nucleophilic substitution sequence. After optimization, this transformation was achieved successfully by using LiHMDS as a base and a slight excess of the corresponding halide compound as the electrophile. The expected substituted
pyridoesters 5 with alkyl, allyl, benzyl and propargyl substituent were thus obtained with yields up to $89 \%$.

Scheme 2. Synthesis of alkyl substituted pyranopyridinones PP1a-g following $\operatorname{method} A$

The pyranopyridinones PP1a-g are easily obtained from $\mathbf{5}$ by an acidic deprotection followed by a lactonisation using 4 eq. of PTSA monohydrate. The unsubstituted pyranopyridinone PP1a was obtained in $20 \%$ isolated yield whereas substituted pyranopyridinones PP1b-g were isolated for the first time in yield from $55 \%$ to $99 \%$ for gem-dimethyl PP1c benefiting from Thorpe Ingold effect for cyclization. ${ }^{[8]}$

We examined a strategy based on the Pinner reaction (method B, Scheme 1) to introduce aromatic substituent on the methylene group of the pyridine ester 4 . It requires the preparation of nitrile analogs of compounds 5 via nucleophilic aromatic substitution of a chloropyridine (Scheme 2 and Scheme 3). ${ }^{[9]}$
The aryl-substituted 2-pyridyl acetonitrile precursors 7a-e were prepared from the protected 2 -chloropyridine 3 and the corresponding aryl or heteroaryl acetonitrile.
We first studied the substitution step by using phenylacetonitrile as a model nucleophile (Table 1). ${ }^{[10]}$ When treated with 3 equivalents of LiHMDS in the presence of 2 equivalents of phenylacetonitrile in toluene at room temperature, the chloropyridine $\mathbf{3}$ gave the expected $\mathrm{S}_{\mathrm{N}} \mathrm{Ar}$ product 7 a in a $62 \%$ isolated yield (Table 1 entry 1 ). However, these conditions were ineffective when using other substituted arylacetonitriles.
Among the few modifications screened (solvent, base, temperature) to improve the yield, the reaction time and the scope of the $\mathrm{S}_{\mathrm{N}} \mathrm{Ar}$ reaction, the use of a large excess of NaH in THF at $70^{\circ} \mathrm{C}$ was found to be the best reaction conditions allowing us to isolate the expected $\mathrm{S}_{\mathrm{N}} \mathrm{Ar}$ product with an optimized yield of $69 \%$ (Table 1, entry 5). Interestingly, this protocol (2 equiv. of phenylacetonitrile in
the presence of 5 equiv. of NaH in THF at reflux 3h), was successively extended to other (Het)arylacetonitrile compounds giving the corresponding $S_{N} A r$ product with yields ranging from 56 to $74 \%$ (Scheme 3). The nucleophilic substitution was also performed on the more hindered phenyl substituted chloropyridine 6 giving the expected product 7 e as a $3 / 1$ mixture of diastereoisomers (Scheme $3)$.

[a] Isolated yield. [b] The expected product was not observed only starting material was recovered.

The intramolecular Pinner reaction (PTSA monohydrate at reflux in toluene) was run on five aryl-substituted 2-pyridyl acetonitrile compounds 7a-e, affording the desired lactones in 39 to $71 \%$ isolated yields. Unfortunately, under these acidic conditions a competitive decyanation of the dipyridyl substituted acetonitrile 7d was observed during the reaction. It is proposed that, under acidic conditions, the protonated electron withdrawing 2-pyridyl substituents activates the benzylic position leading preferentially to decyanation over cyclization.
The high reactivity of the 2-position of the pyridine ring on protected 2-chloropyridylethanol 3 allowed an effective introduction of various substituents on pyranopyridinone PP1 using $\mathrm{S}_{\mathrm{N}} \mathrm{Ar}$ approach.

Scheme 3. Synthesis of aryl substituted pyranopyridinones PP1h-I via method B

Original functionalized pyranopyridinones PP2 possessing the nitrogen atom at the 3 position of the pyridyl ring were prepared
following an unreported selenium-promoted ring closure reaction using pyridoalkynols (Scheme 4). We based our approach on the work of Tiecco et al. ${ }^{[11]}$ who described the conversion of hydroxyl alkynyl phenyl selenides into delta-lactones through proton-induced ring-closure reaction. However, there are limited examples of deltalactones synthesized using this methodology with only one example of a benzofused lactone and no example containing a heteroaromatic ring. We thus first investigated the possible conversion of alkynylpyridyl derivatives into pyranopyridinones PP1 and PP2 using this seleno mediated cyclization. The alkynyl pyridyl carboxaldehydes 8 and 9 were synthesized with good yields from the corresponding bromopyridine derivatives via the Sonogashira reaction using an improved procedure. The best conditions were using $\mathrm{Pd}(\mathrm{Cl})_{2}\left(\mathrm{PPh}_{3}\right)_{2}$ and Cul as catalysts, DABCO as a base instead of $\mathrm{Et}_{3} \mathrm{~N}$ (Scheme 4). ${ }^{[12]}$ The alkynyl deprotection was carried out with potassium carbonate in methanol in 5 min affording the expected alkynyl pyridyl carboxaldehyde 10 and 11 in $95 \%$ and $89 \%$ yield respectively.

Scheme 4. Synthesis of pyranopyridinones PP1a and PP2a-c via method C

Interestingly, when the TMS deprotection was run for longer reaction time, the furo[3,4,c]pyridine 12 was isolated in $54 \%$ yield resulting from an intramolecular 5-exo-dig cyclization (Scheme 4). Reduction of the carbonyl function with $\mathrm{NaBH}_{4}$ in a mixture of THF/ $\mathrm{H}_{2} \mathrm{O}$ was performed on both regioisomers 10 and 11 giving the corresponding alkynols 13 and 14 in good yields. In parallel, methyl and phenyl substituted-alkynols 15 and 16 were obtained successfully by the reaction of 10 or 11 with the corresponding Grignard reagent (Scheme 4). The alkynyl pyridyl selenides 17-20 were prepared from the corresponding alkynols 13-16 with phenylselenyl bromide and two equivalent of copper iodide. ${ }^{[13]}$ Finally, the reaction of selenides 17-20 with an excess of PTSA monohydrate proceeds smoothly in toluene at $120^{\circ} \mathrm{C}$ in 5 h to give selectively pyranopyridinones PP1a and substituted PP2 a-c in moderate yield (Scheme 4).

Thus, we have developed a rapid access to diverse isomers of functionalized pyranopyridinones using three complementary strategies. To increase substituent diversity on pyranopyridinones, we have investigated the synthesis of a new class of semi-rigid compounds based on pyranopyridinones scaffolds with potentially interesting properties as an antifungal, enzyme inhibitors or
antihistaminics. The latter are therapeutics targeting the histamine receptors (H1R to H4R) involved in the regulation of many aspects of diseases such as allergic rhinitis, autoimmune diseases and infection. ${ }^{[14]}$ Among these therapeutic agents, antihistamines H 1 have long been employed to treat allergy.

Figure 2. New class of potential semi-rigid antihistamines based on pyranopyridinones scaffold

First and second generations of H 1 -antihistamines are commonly flexible molecules possessing a diarylmethane moiety i.e. phenbenzamine, cetirizine, doxylamine (Figure 2). ${ }^{[15]}$ However, rotationally constrained molecules of these types are highly desired in order to get more insight to identify the active conformation of histamine itself and thus get more selective H 1 -receptor antagonists. ${ }^{[16]}$ Semi-rigid piperazine substituted 3-isochromones have proved earlier to possess significant antihistaminic activity $(\mathrm{H} 1)$ in isolated guinea pig opening the way to develop other semi-rigid molecules with increased antihistaminic properties through structureactivity relationship studies. ${ }^{[16]}$
In first instance, we have investigated the synthesis of piperazinyl substituted pyranopyridinones, as starting point to develop other original aza analogs of semi-rigid antihistamines described above. PP1a and PP1h were converted into the corresponding bromopyranopyridinones PP1m $\left(R^{3}=H, R^{4}=B r\right)$ and PP1n $\left(R^{3}=\right.$ $\mathrm{Ph}, \mathrm{R}^{4}=\mathrm{Br}$ ) by reaction with 1 equivalent of N -bromosuccinimide. The title compounds PP1o, PP1p and PP1q were then synthesized in yields up to $71 \%$ by condensation of amines such as N -methyland $N$-phenyl piperazine in the presence of trimethylamine or potassium carbonate (Scheme 5).

Scheme 5. A new class of potential analogs of anti-histamines

## Conclusion

In conclusion, two isomers of functionalized pyranopyridinones were synthesized using three different and complementary synthetic methodologies allowing the introduction of various substituents on the lactone ring. We also applied the outlined
synthetic methodologies to prepare semi-rigid analogs of antihistamines with potential biological importance opening the way to develop a new generation of anti-histamines with increased properties. For a future structure-activity relationship studies, other substitution and structural modifications of pyranopyridinones are highly needed and could be easily envisioned based on our developed methodology. The scope of the reaction as well as biological evaluation of these compounds on H 1 receptors are underway in the laboratory and will be reported in due course.

## Experimental Section

General: NMR spectra were recorded on Bruker Avance III 300 MHz or 400 MHz spectrometers at room temperature. Chemical shifts ( $\delta$ ) are expressed in part per million (ppm), reported as s = singlet, $\mathrm{d}=$ doublet, $\mathrm{t}=$ triplet, $\mathrm{m}=$ multiplet; and referenced to the solvent peak of respectively $\mathrm{CDCl}_{3}, \mathrm{CD}_{2} \mathrm{Cl}_{2},\left(\mathrm{CD}_{3}\right)_{2} \mathrm{SO}\left({ }^{13} \mathrm{C}\right.$ NMR: $\delta=77.23$; 53.84; $39.52 \mathrm{ppm} ;{ }^{1} \mathrm{H}$ NMR: $\left.\delta=7.26 ; 5.32 ; 2.50 \mathrm{ppm}\right)$. IR spectra were recorded on ThermoNicolet Avatar 330 FT IR on film. Exact mass measurements were obtained on TQ R30-10 HRMS spectrometer by ESI+ ionization and are reported in $\mathrm{m} / \mathrm{z}$ for the major signal.
Experimental procedures and characterization data for new compounds or compounds made by a new method are listed below. For the experimental procedure and characterization data of the remaining compounds see references: Compounds $2^{17}, 3^{6}, 8^{12}, 9^{12}$, $10^{18}, 11^{19}$ were reported in literature, PP1a ${ }^{4 \mathrm{a}}$ was reported without full characterization. Reagents were purchased as reagent-grade and used without further purification. All anhydrous reactions were carried out in oven dried glassware and under an inert atmosphere of argon. THF and toluene were dried by purification through activated alumina purification columns. Reactions were monitored by analytical TLC on silica gel 60 F254 plates 0.25 mm , and visualized under UV light ( $\lambda=254$ and 354 nm ). Silica gel (SDS 60 ACC 35-70 mm ) was used for column chromatography. Abbreviations: ${ }^{\circ} \mathrm{C}$ : degrees Celsius. DCM: dichloromethane. ## General procedure B for the synthesis of compounds PP1a-g

The appropriate substrate ( $\mathbf{4}$ and $\mathbf{5 b g}$ ) ( 1 eq.) was dissolved in 10 mL of toluene. PTSA. $\mathrm{H}_{2} \mathrm{O}$ (2.5 eq.) was added to the mixture which was stirred at rt for 20 h .40 mL of a mixture of a saturated aqueous solution of $\mathrm{NaHCO}_{3}$ and EtOAc (1:1) were added to the solution. Organic phase was separated. Aqueous phase was extracted with EtOAc ( $2 \times 20 \mathrm{~mL}$ ). The combined organic phases were washed with brine, dried over $\mathrm{MgSO}_{4}$ and concentrated. The resulting residue was purified by silica gel chromatography (Cyclohexane/EtOAc: $5 / 5$ ).

## General procedure C for the synthesis of compounds 7a-7e

$\mathrm{NaH}(60 \%$ in oil, 17 mmol$)$ was added portionwise to a solution of compound 3 or $6(3.4 \mathrm{mmol})$ in THF ( 10 mL ) at room temperature. The corresponding arylacetonitrile ( 4.12 mmol ) was added to the mixture and the reaction mixture was stirred à $70^{\circ} \mathrm{C}$ for 12 h . Water
$(20 \mathrm{~mL})$ was added slowly to stop the reaction. EtOAc $(20 \mathrm{~mL})$ was added and the two layers were separated. The aqueous layer was extracted three times with EtOAc $(20 \mathrm{~mL})$. The combined organic phases were washed with brine $(20 \mathrm{~mL})$, dried over $\mathrm{MgSO}_{4}$, filtered and concentrated. The resulting residue was purified by silica gel chromatography to afford the pure product.

## General procedure D for the synthesis of compounds PP1h to PP1I

Compound 7a-7e ( 3.25 mmol , 1 eq.) was dissolved in 20 mL of toluene. PTSA. $\mathrm{H}_{2} \mathrm{O}$ ( $19.5 \mathrm{mmol}, 6$ eq.) was added and the mixture was vigorously stirred and refluxed at $120^{\circ} \mathrm{C}$ for 4 h . The reaction mixture was cooled to room temperature and poured into a mixture of a saturated aqueous solution of $\mathrm{NaHCO}_{3}$ and $\mathrm{EtOAc}(1 / 1)(50 \mathrm{~mL}$ +50 mL ). Water was added and the layers were separated. The aqueous layer was extracted with EtOAc ( 100 mL ). The combined organic layers were washed with water ( 100 mL ), a saturated aqueous solution of $\mathrm{Na}_{2} \mathrm{CO}_{3}(50 \mathrm{~mL})$ and brine $(50 \mathrm{~mL})$. Finally, the organic layer was dried over $\mathrm{MgSO}_{4}$ and concentrated to afford the title compound. The residue was purified by silica gel chromatography.

Original pyranopyridinones containing polyfunctionalized delta-lactones ring have been synthesized using three concise and efficient synthetic methodologies. Potential semi-rigid analogs of antihistamines containing a pyranopyridinone scaffold have also been prepared using the outlined synthetic methodologies.
