ABSTRACT

We revise the taxonomy of the *Sylvia cantillans* complex, a group of phenotypically distinct warblers mainly parapatrically distributed around a large part of the Mediterranean basin. We redefine the species limits using a combination of mitochondrial and nuclear markers and we objectively link available names to the genetically-defined lineages by genotyping the surviving type specimens. In addition, the study of archival documents clarifies the exact composition of type series and provides further evidences for the identification of lost types. These results support the recognition of three species-level taxa: Moltoni's Warbler, *Sylvia subalpina* Temminck, 1820, monotypic (north-central Italy, Corsica, Sardinia, Balearics); the Western Subalpine Warbler, *Sylvia iberiae* Svensson, 2013, monotypic (North Africa, Iberia, southern France, extreme north-west Italy); the Eastern Subalpine Warbler, *Sylvia cantillans* (Pallas, 1764), polytypic, with subspecies *S. c. cantillans* (Pallas, 1764) (southern Italy, Sicily) and *S. c. albistriata* (Brehm CL, 1855) (Balkans, Greece, western Turkey).

Keywords: *Sylvia cantillans*, types, taxonomy, species limits

1. INTRODUCTION

The Subalpine Warbler *Sylvia cantillans* complex includes a number of phenotypically distinct forms mainly parapatrically distributed around a large part of the Mediterranean basin (Dickinson & Christidis, 2014; del Hoyo & Collar, 2016). Following the prevailing biological species concept (Mayr, 1942), a single species was generally recognised during the twentieth century (Table 1). Using plumage characters, the different populations were separated in three subspecies: the nominate *cantillans* from Portugal, Spain, France and Italy, including Sicily, Sardinia and Corsica, the subspecies *inornata* for the North African populations and the subspecies *albistriata* restricted to the Balkans, Greece and the Aegean side of Turkey.

Although plumage characters among subspecies are subtle and often better appreciated when museum series are compared, field observations revealed that birds from Sardinia, Corsica and the Balearics shared a peculiar, markedly different contact call, unknown in mainland populations (Lemaire, 1973; Bergmann, 1976; Cody & Walter, 1976; Thibault, 1983; Gargallo, 1994). Moreover, Gargallo (1994) and Shirihai *et al.* (2001) pointed out that the populations in the central Mediterranean islands shared a distinct moult strategy and pinkish male underparts, without any rusty, chestnut or orange shade. For these populations they resurrected the subspecies *moltonii*, previously subsumed in the synonymy of the nominate form, presumably under the influence of Vaurie (1954). The name *moltonii* was quickly accepted by Dickinson (2003) and the *Handbook of the Birds of the World* (del Hoyo *et al.*, 2006).

Further field observations by Festari *et al.* (2002) and a subsequent detailed survey across mainland Italy (Brambilla *et al.*, 2006) indicated that the same vocally distinct populations occurs in both the central Mediterranean islands and in central-northern Italy, where it overlaps with the populations occurring both further south and in extreme north-west Italy bordering France. The largely parapatric distribution, the distinct call types and the lack of mixed pairs at syntopic sites, in addition to the differences in the moult strategy and the differential response to playback test to the same *vs.* other songs, strongly suggested that this distinctive population could be ranked as a separate species (Brambilla *et al.*, 2006, 2008a,b).

A phylogeographic analysis using a single mitochondrial locus demonstrated that the *Sylvia cantillans* complex consists of four deeply divergent, mostly parapatric lineages (Brambilla *et al.*, 2008a), with the most divergent lineage indeed uniting birds from north-central Italy with those from the central Mediterranean islands (Corsica, Sardinia, Balearics). The southern Italian populations form a different clade, sister to the Balkan lineage, and a further group covers Spain and France. Although the four-clade phylogeographic structure is well supported, the number and limits of species to be recognised in the complex still remained to be clarified. In addition, the

appropriate names for taxa within the complex were also contentious. On the one hand, multiple traits (see above), coupled with genetic distinctiveness, definitively identify the populations inhabiting central Mediterranean islands and central-northern Italy as a distinct species, the Moltoni's Warbler (*Sylvia subalpina* syn. *Sylvia moltonii*; Brambilla *et al.*, 2008c). On the other, the same study stated that “when more data are provided [...] a further subdivision into two branches, i.e. southern *cantillans* and *albistriata* on the one side and western *cantillans* on the other, representing two different (allo)species, could be expected”, which could be regarded as phylogenetic species (Brambilla *et al.*, 2008c). The two-species approach was then followed by most authors (see below), although a three-species split was already foreseen as very likely on the basis of the complex phylogeography; eastern and western clades could be regarded as two allospecies, the names for which remain to be defined (Brambilla, 2013).

The split into three species was then proposed by Svensson (2013a, b), who combined available phenotypic and mitochondrial evidences (Gargallo, 1994; Shirihai *et al.*, 2001; Brambilla *et al.*, 2008c). He recognized three species in the complex: *Sylvia subalpina* (north-central Italy and central Mediterranean islands); *S. cantillans*, with subspecies *cantillans* (South Italy) and *albistriata* (Balkans, Greece, Turkey); and *S. inornata*, with subspecies *inornata* (North Africa) and the newly described *iberiae* (Portugal, Spain, France). Except for the transfer of these taxa to the genus *Curruca* following the split of the genus *Sylvia*, the three-species approach was incorporated into the fourth edition of the *Howard & Moore Checklist* (Dickinson & Christidis, 2014). However, a more conservative two-species approach remains prevalent (Sangster *et al.*, 2015; del Hoyo & Collar, 2016; Clements *et al.*, 2018; Gill & Donsker, 2019), with a polytypic *Sylvia cantillans* including three or four subspecies (i.e. *cantillans*, *albistriata*, *inornata*, *iberiae*) and a monotypic *S. subalpina*, though Clements *et al.* (2018) restrict *subalpina* to the central Mediterranean islands and maintain birds from the central-northern Italy in *cantillans*. Furthermore, as stated above, the continuous recognition of the North African as populations distinct from the rest of the complex relies on no genetic evidence and thus needs to be tested.

The current nomenclatural treatment is even more controversial, both at the species and subspecies level. Baccetti *et al.* (2007) provided a brief summary of species names available for the complex and recommended to synonymize *Sylvia cantillans moltonii* Orlando, 1937, with *Sylvia subalpina* Temminck, 1820. Further nomenclatural remarks were presented by Svensson (2013a), in connection with the designation of a neotype for *Sylvia cantillans* Pallas, 1764. However, the surviving type material has never been studied critically, and a number of statements concerning the type specimens of *Sylvia subalpina* Temminck, 1820, seem to be cited repeatedly from secondary sources (Baccetti *et al.*, 2007; Svensson, 2013a).

In the present contribution, we address some systematic, taxonomic and nomenclatural points to provide a robust revision of the *Sylvia cantillans* complex starting from the examination of the type material still available. Namely, we aim at: i) expanding the phylogeographic analysis of Brambilla *et al.* (2008c) with more comprehensive sampling including the Maghreb, thus covering the entire range of the complex, ii) inferring the species limits integrating mitochondrial and nuclear data, iii) objectively linking available names to genetic lineages by genotyping the surviving historical types, iv) studying original archival documents to provide further evidences for the identification of the lost types.

2. MATERIALS AND METHODS

2.1. Sampling

We obtained fresh samples, either tissue, blood or feathers, for 91 individuals covering the entire range of the *Sylvia cantillans s.l.* complex (Table 2). We paid special attention to using samples obtained from breeding individuals. Breeding status was inferred directly for ringed birds, using behaviour (singing males trapped with playback) or examination of the cloacal protuberance in males and presence of brood patch in females as proxies. We further assumed a breeding status for specimens sampled from mid May to the beginning of July, i.e. during the full breeding period and outside the know migration time for the taxa belonging to the complex. One of the specimens from which we obtained a tissue sample was selected as neotype of *Sylvia subalpina* Temminck, 1820 (see below). We supplemented the fresh sample dataset with toe-pad samples from four study skins to have a better coverage for some key geographic areas.

In addition, we included toe-pad samples from surviving historical types: one syntype of *Sylvia leucopogon* Meyer, 1822; the lectotypes of *Curruca albistriata* Brehm, 1855 and *Sylvia subalpina inornata* Tschusi, 1906; two syntypes of *Sylvia cantillans moltonii* Orlando, 1937; and the supposed lectotype of *Sylvia cantillans moltonii* Orlando, 1937.

Museum acronyms are reported in Table 2.

2.2. Laboratory work

The tissue samples were extracted using the Qiagen DNA Mini Kit, following the manufacturer's protocol or the modified protocol described in Zuccon & Ericson (2010) for the toe-pad samples. All extractions and PCR set-up for toe-pad specimens were carried out in separate spaces, dedicated to handling archival DNA.

For the phylogeographic analysis, we amplified two mitochondrial genes, cytochrome *b* (cytb) and cytochrome oxidase I (COI). The cytb was amplified either as a single fragment using the primers 4L and 1137H, or in two fragments using the internal primers 538L and 662H, following the protocol in Brambilla *et al.* (2008a). The COI gene was amplified using the primers COI-ExtF and VerteR1, following the protocol of Johnsen *et al.* (2010). The toe-pad samples were amplified in a series of short, overlapping fragments of 150-300 bp, using a large set of internal primers, designed using GeneFisher2 (Giegerich *et al.*, 1996) and the alignment obtained from the fresh samples (Supporting Information Table S1). For a subset of specimens (60 individuals) we sequenced also three nuclear introns, using published primers and amplification protocols: β -fibrinogen intron 5 (bFib5, Fuchs *et al.*, 2004), glyceraldehyde 3-phosphate dehydrogenase intron 11 (GAPDH, Fjelds  *et al.*, 2003), and adenylate kinase intron 5 (AK1, Shapiro & Dumbacher, 2001).

The PCR products have been Sanger sequenced bidirectionally using an ABI 3130 sequencer (Applied Biosystem) and the sequences assembled using CodonCode Aligner (LI-COR, Inc, USA). To unambiguously determine the allele phase of nuclear loci we resequenced the same products that showed more than one heterozygous position using an Ion Torrent PGM, following the protocol of Dettai *et al.* (2012).

2.3. Phylogenetic analyses

Selection and recombination

Prior to the molecular analyses, we tested if our datasets conformed to the hypothesis of neutral evolution and if recombination events could be detected in the intron loci. Selection acting on the mitochondrial protein coding genes was tested using the McDonald-Kreitman test (McDonald & Kreitman, 1991), with significance assessed using the Fisher's exact test (threshold value of $\alpha=0.05$), as implemented in DnaSP v. 6.0 (Librado & Rozas, 2009). For the nuclear introns we used the Hudson-Kreitman-Aguad  (HKA) test (Hudson *et al.*, 1987), in the version implemented in the HKA software (https://bio.cst.temple.edu/~hey/hka_manual). We used the GARD (Genetic Algorithm for Recombination Detection) software, as implemented in HyPhy (Kosakovsky Pond *et al.*, 2005, 2006) to detect whether the nuclear loci were subject to recombination.

Phylogenetic trees

The cytb and COI sequences were combined in a single mitochondrial dataset, analyzed under the maximum likelihood criterion using RAxML v. 8.2.12 (Stamatakis, 2006), implemented on CIPRES portal (Miller *et al.*, 2010). We imposed a partitioned analysis, selecting the GTR+ Γ +I substitution model and random starting tree. The nodal support was estimated using 100 bootstrap

replicates. The topology was rooted using other six *Sylvia* species (see Table 2) that are among the most closely related to *Sylvia cantillans* in the genus phylogenies of Shirihai *et al.* (2001) and of Böhning-Gaese *et al.* (2003).

Allele networks

We built a separate minimum spanning network for each nuclear locus with PopART 1.7 (Leigh & Bryant, 2015). We recoded indels as a single bp mutation event, substituting the indel with a base different from the one occurring at that position in the remaining alleles.

The nuclear loci were combined in a multi-locus network using POFAD v. 1.07 (Joly & Bruneau, 2006) and SplitsTree v. 4.0 (Huson & Bryant, 2006), selecting uncorrected pairwise (p) distances for POFAD and using the standardized matrix for the network reconstruction.

Population genetics analyses

We used Arlequin 3.5 (Excoffier & Lisher, 2010) to calculate standard diversity indices and perform population genetics analyses. We calculated population pairwise F_{st} to estimate population differentiation due to genetic structure within the three main lineages recovered by phylogenetic analyses. We used Fu's F_s and Tajima's D tests (1000 replicates) to detect signatures of population expansion. Tajima's D and Fu's F tests have been shown to be especially sensitive to departure from population equilibrium as in case of a population expansion or selection (Excoffier & Lisher, 2010). As we did not detect any signature of selection in our data set using the McDonald-Kreitman test (McDonald & Kreitman, 1991), we interpret here significant negative values of Tajima's D and Fu's F as resulting from population expansion.

2.4. Type material reassessment

We assembled a full list of names applied to the *Sylvia cantillans* complex over time. For each we studied the original description, tried to locate the associated type material and, when relevant, we consulted archival documents to find additional information that could help to clarify origin, identification and whereabouts of types.

3. RESULTS

3.1. Phylogenetics

The *cytb* and *COI* sequences showed no unusual mutation patterns, indels or stop codons, suggesting that they were of mitochondrial origin. Evidence of selection was detected in neither the

mitochondrial genes (MK test, cytb: $P=1.000$, COI: $P= 0.342$) nor in the nuclear introns (HKA test, sum of deviations: 1.4162, d.f.=2, $P= 0.49257$), and no recombination hotspots were identified in the introns by the GARD algorithm.

Mitochondrial DNA phylogenetic tree

We obtained 1090bp of cytb and 648bp of COI genes for 97 individuals (91 fresh and 6 study skin specimens, including the neotype of *Sylvia subalpina* Temminck, 1820 and two syntypes of *Sylvia cantillans moltonii* Orlando, 1837). Due to specimen age and the low quality of the DNA extracted, we recovered only partial mitochondrial sequences from the other type specimens: 232bp (cytb) for the syntype of *Sylvia leucopogon* Meyer, 1822; 242bp (cytb) for the lectotype of *Curruca albistriata* Brehm, 1855; 769bp (cytb) for the supposed lectotype of *Sylvia cantillans moltonii* Orlando, 1837; and 857bp (cytb) and 456bp (COI) for lectotype of *Sylvia subalpina inornata* Tschusi, 1906. All new sequences have been deposited in Genbank with the Accession Numbers MN642106-MN642549 (Supporting Information Table S2).

The mitochondrial data define five major, well supported clades in the Maximum Likelihood tree: 1, central-northern Italy; 2, the western Mediterranean islands (Corsica, Sardinia and Balearics); 3, North Africa, Spain, France and the westernmost end of Italy; 4, central-southern and southern Italy (including Sicily), with scattered occurrences in northern Italy too; 5, the Balkans and Greece (Fig. 1, 2). Clades 1 and 2 on the one side, and 4 and 5 on the other, are sister groups and these nodes receive high bootstrap support, but the branching order of the three major lineages departing from the basal nodes remains unsupported in the mitochondrial tree. We observe very little genetic intraclade variability (mean uncorrected p -distance 0.08-0.22% and 0.06-0.30% for cytb and COI, respectively, Table 3) and no clear geographic structure except within clade 3, where North African haplotypes do not mix with their European counterparts (see population genetics results). Within clade 5, three individuals form a paraphyletic lineage, basal to the other individuals.

Position of the types in phylogenetic trees

The phylogenetic reconstruction unambiguously allocates the neotype of *Sylvia subalpina* to clade 1, the types of *Sylvia cantillans moltonii* (syntypes and supposed lectotype) and *S. subalpina inornata* to clade 2, the syntype of *S. leucopogon* to clade 4 and the lectotype of *Curruca albistriata* to clade 5.

Nuclear allele networks and population genetics

For 60 individuals, selected from all clades identified above, we obtained 547bp and 275bp for the GAPDH and bFib5 introns, respectively. The allele networks of both genes are strongly structured.

The central part of the GAPDH network is formed by alleles recovered in individuals belonging to the mitochondrial clades 4 and 5 (Fig. 3B). These are almost completely separated from those obtained from individuals in clades 1 and 2 on one side and from clade 3 on the other. A similar network structuring is observed for the bFib5 gene (Fig. 3A). Except for the second most common allele recovered, which is shared by all mitochondrial clades, the individuals from clade 1+2, 3 and 4+5 occupy different portions of the network.

The neat geographic separation of haplotypes observed in the mitochondrial clade 1 and 2 (Fig. 1), for which the F_{st} value is highly significant (Table 4), is not matched by the nuclear loci which show full admixture (Fig. 3A, B). Accordingly, the nuclear F_{st} values between these two clades are very low and not significant (Table 4). The most common alleles observed in clade 1 and 2 are equally shared by the two mitochondrial clades in both networks, with only 18-21% of alleles private to either lineage.

For alleles recovered from individuals in mitochondrial clades 4 and 5 there is some overlap, with the common alleles shared by individuals belonging to the two clades. However, a larger proportion of alleles are private to either clade (25% in GAPDH and 58% in bFib5) and F_{st} values are highly significant (Table 4), suggesting again that the evolutionary trajectory of these mitochondrial groups is mostly independent from each other.

Although the genetic distance within the mitochondrial clade 3 is very low (mean uncorrected p -distance 0.2 %), we found a significant population differentiation for the mitochondrial DNA and the nuclear intron GAPDH between the North African and the European populations (Table 4) suggesting a modest level of gene flow between the two sides of the western Mediterranean basin. Mitochondrial genetic distance between clade 1 and clade 2 (approximately 1%) is slightly lower than that measured between clade 4 and clade 5 (Table 3).

The multi-locus network based on the two nuclear introns shows a strong structure, in part matching the mitochondrial tree (Fig. 3C). The individuals from mitochondrial clades 1 and 2 intermix without structure in a single group apart from the other specimens. Those in clades 4 and 5 appear to be closely related, with specimens from each clade clustering on distinct sides of the same network branch with limited admixture. Only two specimens from clade 4 appear to be closer to those of the other clade than to their own. All F_{st} values between clade 4 and clade 5 are highly significant (Table 4). Clearly distinct from all others are the specimens from clade 3.

Haplotype diversity is high for the five mitochondrial clades, and nucleotide diversity values reach moderate and similar values for all clades (Table 5).

For a reduced number of individuals (32 specimens), and focusing now on clades 4 and 5, we obtained 570bp for the AK1 intron 5. The strong network structure confirms the segregation of specimens from clade 3 on one side, placing those from clades 1 and 2 together without any

separation, and those from clade 4 and 5 together, showing a significant allele sharing, with only 25% of private alleles (Fig. 4A). Similarly, the multilocus network based on the three alleles confirms a three-way partition. Although the specimens in clades 4 and 5 cluster on opposite sides of the same branch, their genetic distance is overall reduced and some individuals from both clades appear closer to those of the opposite group (Fig. 4B).

Population expansion

Our results strongly suggest a pattern of population expansion for all mitochondrial clades but one. No signs of population expansion were detected for the North African population in clade 3 (Table 6). We acknowledge that larger sample sizes would be required to confirm this last result.

3.2. Reassessment of available names in the *Sylvia cantillans* complex

Motacilla (cantillans) [Pallas], 1764, *Adumbratiunculae* p.4, in: [Vosmaer], 1764. *Beredeneerde catalogus, van eene, by uitstek fraaye en weergaalooze verzameling, zoo van inlandsche als uitheemsche vogelen, viervoetige en gekorvene dieren.*

Type locality: "Uit Italie" [i.e. from Italy, no further information]; restricted to "Sicily" by Svensson (2013a).

Type: syntypes presumed lost; neotype NHMUK 1909.11.18.50, first summer male, collected at Ficuzza, Sicily, on 23 May 1906, by Alphonse Robert; designated by Svensson (2013a). A picture of the neotype is available in Svensson (2013a).

Notes: the new species was based on two mounted syntypes, male and female, formerly in the private Vroeg collection and sold at auction on 6 October 1764 (Vosmaer, 1764; Sherborn, 1905; Rookmaaker & Pieters, 2000). According to handwritten notes on a copy of the sale catalogue (Vosmaer, 1764) kept at the Koninklijke Bibliotheek (Den Haag), the lot comprising the two syntypes was bought by Vosmaer for f 5.12. and very likely the specimens entered into the natural history cabinet of Stadtholder William V, where Vosmaer was curator at the time. After the invasion of the Netherlands by the French revolutionary army in 1795, the Stadholder's cabinet was dispersed. The whereabouts of the royal collections is rather complex. The largest part was looted and transferred to the MNHN, where the specimens were either integrated into the museum collections, further dispersed or returned to the Netherlands after 1815. A part of the collection was apparently hidden locally and later it was incorporated into several smaller Dutch collections, from where the specimens were further dispersed or reached the museums in Leiden, Groningen, Utrecht and Amsterdam (Boseman, 1970; Boyer, 1971; Pieters, 1980). At present, the whereabouts of the

syntypes is unknown. They are not present at the MNHN nor at Naturalis Biodiversity Center, Leiden, and in all evidence they are lost.

Assuming that the syntypes originated from Italy, it is most likely that they belong to the populations from the southern part of Italy because of the brick-coloured breast (“subtus testacea”) mentioned in the original description. The neotype designation (Svensson, 2013a) objectively links this name to clade 4.

Sylvia Rhodogastra Rafinesque, 1810, *Caratteri di alcuni nuovi generi e nuove specie di animali e piante della Sicilia* p.7.

Type locality: not explicitly stated, but Sicily by inference.

Type: not explicitly stated.

Notes: the description lacks diagnostic characters and it could apply to several *Sylvia* warblers (“Bigia scura al disopra, rosastra al disotto, rostro, ale e coda fosche, le penne esterne della coda terminate di bianco, piedi fulvini.” [warbler dark above, pinkish below, bill, wing and tail dark, outer tail feathers ending white, feet tawny]). It is not clear if the new species was based on specimens or observations, but the entire collection assembled by Rafinesque during his residence in Sicily is lost. In part, it was lost at sea with the shipwreck of the "Union" during Rafinesque's voyage to the United States in 1815, in part abandoned in Palermo and subsequently dispersed (Lentini, 2012). Although Hartert & Steinbacher (1932-1938: 278) included the name *rhodogastra* in the synonymy of *Sylvia cantillans*, we concur with Salvadori (1872) that the name is not clearly identifiable and we treat it as a *nomen dubium*. However, it remains available for nomenclatural purposes, *contra* Baccetti *et al.* (2007).

Sylvia Turdella Rafinesque, 1810, *Caratteri di alcuni nuovi generi e nuove specie di animali e piante della Sicilia* p.7.

Type locality: not explicitly stated, but Sicily by inference.

Type: not explicitly stated.

Notes: with an even shorter description (“Bigia rossiccia scura, biancastra al disotto, rostro e piedi foschi.” [dark reddish warbler, whitish below, dusky bill and feet]), this name could also apply to several *Sylvia* warblers. Although identified as a senior synonym of *Sylvia subalpina* by Trischitta (1922), we concur with Salvadori (1872) in considering *turdella* a *nomen dubium*. Also in this case, it is not clear if the name was based on specimens or observations and all evidence as to whether a type ever existed is now lost (Lentini, 2012). The name *turdella* remains available for nomenclatural purposes.

Sylvia subalpina Temminck, 1820, *Planches Coloriées* livr.I pl.6.

Type locality: “près de la ville de Turin” [i.e. near the town of Turin, NW Italy], from the subsequent description in Temminck (1820b: I p.214).

Type: holotype Regio Museo di Zoologia, Turin, no. 1977, male, collected near Turin on 9 September 1819; disposed of in 1827 due to insect damage. A neotype is here designated, see below.

Notes: the name is invariably cited from Temminck's second edition of *Manuel d'Ornithologie* (Temminck, 1820b: I p. 214). However, the *Manuel* was published only in October 1820, as indicated on the title page as well by its inclusion among the newly published books in the 21 October 1820 issue of the *Bibliographie de la France* (Anonymous, 1820). The name was actually first made available in the first livraison of the *Planches Coloriées* (Temminck, 1820a), published in August 1820 (see Dickinson, 2001 for the publication date and Dickinson, 2012 for the name spelling).

Bonelli sent the holotype to Temminck and it was clearly the model used by Prêtre, the artist, for the plate (“Cette espèce du midi de l'Europe m'a été communiquée par M. Bonelli, qui me fit l'amitié de m'envoyer à Paris l'individu unique qu'il possédait, pour en publier la description dans le *Manuel d'Ornithologie*, et le figurer dans nos planches coloriées” [This species from southern Europe has been passed on by Mr Bonelli, who did me the kindness of sending to Paris the only specimen he owned, to publish the description in the *Manuel d'Ornithologie*, and figure it in our coloured plates], Temminck, 1823), *contra* Baccetti *et al.* (2007).

The text accompanying the plates of the first 20 livraisons of the *Planches Coloriées* was issued well after the plates, with the text of plate 6 distributed only in June 1823 (Dickinson, 2001). This explains the apparent contradiction in the text, where Temminck indicates that a single female specimen was available for the illustration, but at the same time he also describes the male plumage, and refers to additional specimens obtained since.

In the first published description, Temminck (1820b) reiterated that the specimen is an adult female collected in spring (“La vieille femelle au printemps ... On ne connaît point encore la livrée du male; l'individu tué dans les environs de Turin est une femelle” [the old female in spring ... the male plumage is not known, the specimen killed near Turin is a female]), but this contradicts Bonelli's entry in the museum catalogue. The “*Catalogo numerico degli Animali Vertebrati del R. Museo*” [Numerical catalogue of vertebrate animals of the Royal Museum] was started by Bonelli in 1820 and it is still present in the archive of the Biblioteca del Dipartimento di Scienze della Vita e Biologia dei Sistemi (University of Turin). In the entry for the type specimen, Bonelli indicates that it was a male collected near Turin on 6 September 1819 and subsequently disposed due to insect

damage (Fig. 5). According to Salvadori (1916) the specimen was supplied by Alason, a regular Bonelli's correspondent.

At the meeting of the Reale Accademia delle Scienze of Turin on 27 February 1820 Bonelli read the first part of a contribution on new bird species observed in Piedmont since 1811 that included also the description of *Sylvia subalpina* (Archives of the Accademia delle Scienze, Turin; Gené, 1834). For unknown reasons the rest of the manuscript was never presented at the Academy meetings and it was never published. Although the manuscript survived Bonelli's death in 1830 and it was examined by Gené (1834), the present whereabouts are unknown and it might have been lost (P. Passerin d'Entrèves, pers. comm.). It is not present in any of the libraries or archives holding Bonelli's material (Archive of the Accademia delle Scienze, Turin; Biblioteca Reale, Turin; Biblioteca Nazionale Universitaria, Turin; Biblioteca del Dipartimento di Scienze della Vita e Biologia dei Sistemi, University of Turin).

Sylv.[ia] Leucopogon "Heckeli" Schinz, 1821, *Das Thierreich* I p.556.

Type locality: "Sizilien" [Sicily].

Type: not explicitly stated, but apparently based on the same type series as *Sylvia leucopogon* Meyer, 1822 (see next section).

Notes: the name *Sylvia leucopogon* has always been attributed to Meyer (see below). Although systematically omitted from all checked synonymies, the name published by Schinz in his translation of Cuvier's *Règne Animal* is perfectly valid and predates Meyer's name. Like Meyer, Schinz credited Heckel for the authorship of the new species and used the name selected by Heckel himself (it is under *Sylvia leucopogon* that in 1821 Heckel's specimens were entered into the collection register of the NHMW, see next section).

Schinz was secretary of the Naturforschenden Gesellschaft in Zurich and curator of the zoological collection. The newly established Zoologische Museum at Zurich University bought the zoological collection in 1837, together with a handwritten catalogue ("*Verzeichniss der zoologischen Sammlung*" [Register of the zoological collection]) that still exists in the museum archives. One specimen is listed in the catalogue under the name *Sylvia leucopogon*, indicating that very likely Schinz received at least one specimen from Heckel. However, that specimen is no longer extant in the collection (D. Hansen, M. Schenkel, pers. comm.).

Schinz's description is surprisingly similar in the word choice and has almost the same sentence order as the one of Meyer's (1822) (Fig. 6). Moreover, the description mentions the eye colour, a character not observable in a study skin. It is highly probable that Heckel supplied a description, perhaps the same to both Schinz and Meyer, and Schinz used it as draft to prepare his

own text. In this case, in accordance with Art. 72.1.1, 72.4.1 and 72.4.1.1 (ICZN, 1999), all specimens collected by Heckel must form the type series of Schinz's name (see also below).

Sylvia leucopogon "Heckeli" Meyer B, 1822, *Zusätze und Berichtigungen zu Meyers und Wolfs Taschenbuch der deutschen Vögelkunde* p.91.

Type locality: "Sizilien" [Sicily].

Type: surviving syntypes NHMW 42230 (old number 1821.LXXV.13a), adult male; NHMW 43687 (old number 1821.LXXV.13), adult male; NHMW 60134 (old number 1821.LXXV.13c), adult female; NHMW 35603 (old number 1821.LXXV.13d) adult female (Supporting Information Fig. S1). All four were obtained in 1820 by Johann Jakob Heckel in Sicily, the males in Palermo and the females in Terranova (today Gela). The specimen SMF 78882 (Italy) in the Senckenberg Naturmuseum (Frankfurt am Main) might represent a fifth surviving syntype, but its status remains questionable (Supporting Information Fig. S2). The specimens RMNH 171709 and RMNH 171711 in the Naturalis Biodiversity Center (NBC, Leiden) bear identical Temminck style labels and one of the two should be another syntype (Supporting Information Fig. S3). Other lost syntypes include one female formerly in the Naturalis Biodiversity Center (Leiden), and at least one specimen formerly in the Zoologische Museum (Zurich University).

Notes: in the original description Meyer states that a male collected in Sicily was sent by Heckel from Vienna to Frankfurt. This specimen is described in detail. However, the authorship is attributed to Heckel ("Heckeli"), the text also contains a shorter description with slightly different wording for the female as well as the male, and the eye colour, a character obviously not observable in a skin, is mentioned. In addition, as remarked above, word choice and sentence order are surprisingly similar in Meyer's and Schinz's descriptions (Fig. 6). All this strongly suggests that Heckel supplied Meyer with not just one specimen, but with a written description as well and that he selected the name *leucopogon* (already used in 1821 in the collection registers of the NHMW). We conclude that Meyer description is based on his own study of the male specimen sent to Frankfurt, combined with information supplied by Heckel, who in turn based his diagnosis on all specimens collected by him during his Italian travel in 1820. In agreement with Art. 72.1.1, 72.4.1 and 72.4.1.1, we assume that all specimens collected by Heckel form the type series of *Sylvia leucopogon* Meyer B, 1822.

The precise number of specimens collected by Heckel is not known and at present the archives in the NHMW have no notebooks or documents relative to his Italian travel. However, apparently no less than 8 specimens were collected. The male specimen sent to Frankfurt could not be located unambiguously, although one male specimen from Italy (SMF 78882) in the Senckenberg Naturmuseum (Frankfurt am Main) belongs to the old collection and it might be the

specimen received by Meyer. Unfortunately, the lack of original labels or other archival evidences casts doubts on its type status (G. Mayr, pers. comm.). The specimen sent to Schinz in Zurich is apparently lost (see above). According to the museum register, six specimens were bought by the NHMW in October 1821 from Heckel (original numbers 1821.LXXV.13-1821.LXXV.13e). A subsequent annotation in the catalogue indicates that the male 1821.LXXV.13b and the female 1821.LXXV.13e were sent to Leiden at an unknown date, but obviously before 1824 because these specimens are those figured and described by Temminck (1824) in the *Planches Coloriées*, pl. 251 fig. 2-3 and accompanying text. The whereabouts of the female is unknown, it is no more present in the NBC collection and it is presumably lost. On the other side, there are two mounted adult male specimens, RMNH 171709 and RMNH 171711, with identical Temminck style labels, both referring to pl. 251 f. 2, and both collected in Italy. Unfortunately the preparation style appears to be very similar if not identical in both specimens, and both match well the illustration in pl. 251. Likely the two specimens received the same label in error, but at present it is not possible to identify unambiguously the actual syntype. The other four specimens are still present in the NHMW collection (Pelzeln & Lorenz, 1887). Of these, NHMW 43687 is mounted, while the other three are relaxed round skins, all retaining an old label. The exact collection date is not given, but Heckel returned in Vienna during the summer of 1820 to be appointed taxidermist at the NHMW in August (Svojtka *et al.*, 2012), suggesting that the specimens were obtained during spring or early summer of the same year. Although the specimens are partly discoloured, clearly suffering from exposure to light and dust when mounted, it is still possible to appreciate the brick-red throat and breast in males contrasting with the paler flanks and belly. The colour agrees well with the known plumage variability in populations breeding in central-southern Italy.

Curruca albistriata Brehm CL, 1855, *Vogelfang* p.229.

Type locality: "In Egypten, wahrscheinlich auch in Südosteuropa" [in Egypt, probably also in South-Eastern Europe].

Type: lectotype AMNH 455634, adult male, collected in Egypt; lectotype designation by Hartert (1918: p.33) (Supporting Information Fig. S4).

Notes: originally in Brehm Collection, the type was acquired by Rothschild in 1900 and entered into his collection, from where it reached the AMNH in 1932 (Hartert, 1918). The lectotype status was provisionally accepted by Le Croy (2008: 74). This specimen label bears three names: "*Curruca albigularis*" and "*albistriata*" on one label side, both crossed out, and "*Curruca leucopogon orientalis*" on the other side (Supporting Information Fig. S4). In the original reference, there is no indication of the number of specimens involved. However, in the catalogue of the Brehm collection published by Alfred Brehm (1866) after his father's death, a single specimen is listed

under the name "*Curruca leucopogon orientalis*". The specimen could thus have the status of holotype, making Hartert's selection (1918) irrelevant.

Curruca leucopogon major Brehm AE, 1866, *Verzeichniss der nachgelassenen Sammlung* p.6.

Curruca leucopogon minor Brehm AE, 1866, *Verzeichniss der nachgelassenen Sammlung* p.6.

Curruca leucopogon orientalis Brehm AE, 1866, *Verzeichniss der nachgelassenen Sammlung* p.6.

Notes: these three names are used in the published list of specimens in the Brehm Collection. All three lack any description or reference, making them *nomina nuda*, as indicated by Hartert (1910).

See above for the use of the name *Curruca leucopogon orientalis*.

Sylvia subalpina inornata Tschusi, 1906, *Ornithologische Jahrbuch* 17(3-4) p.141.

Type locality: "Tunis".

Type: lectotype ZSM 17.2694, originally no.636 in the second Tschusi Collection, adult male collected at Tunis, in May 1906; lectotype designation by Tschusi (1906b: 108) (Supporting Information Fig. S5).

Notes: the use of the plural ("Grasmücken" [warblers]) and a wing length range are clear indication that the new taxon was based on more than one specimen (Tschusi, 1906a). The type series was originally in the second Tschusi Collection. Despite its inclusion in the published list of Tschusi types deposited in the NHMW (Tschusi, 1906b), the type series together with other 1600 Tschusi specimens passed into Alfred Laubmann's private collection at an unknown time, but probably around 1912. Eventually, the Laubmann collection was in turn incorporated into the Zoologische Staatssammlung München in 1916 (Gengler, 1924; Hellmayr, 1928).

The ZSM collection holds four specimens with original Tschusi labels. The specimen with number no. 694 (Tunis, May 1911, now ZSM 17.2695) must be excluded from the type series because of a collection date later than the original description. Of the remaining three, the adult male no. 636 (Tunis, May 1906, now ZSM 17.2694) is the lectotype after Tschusi's designation (1906) (Art. 74.5), and the adult female no. 637 (Tunis, May 1906, now ZSM 17.2696) is from all evidence a paralectotype. The last specimen, adult male no. 1052 (Tunis, May 1906, now ZSM 17.2697) most likely does not belong to the type series. Although its collection locality and date are compatible with the original description, the label bears a much higher registration number. The Tschusi catalogue of his second collection has not been located, but very likely it passed first into Laubmann's possession together with the bird collection and then transferred to the ZSM, whose archives were lost during WWII (Fittkau, 1992). However, an examination of other Tschusi catalogues in Vienna, and in particular the collection dates and registration order, strongly suggests that he registered the new specimens as they arrived, indicating that the specimen no. 1052 was

likely received much later than the others, and thus should not be included in the original type series. This is further supported considering that all specimens were supplied by Marius Blanc, a French dealer of natural history specimens based in Tunis (Mars, 1969). A perusal of Tschusi catalogues in NHMW indicates that Blanc supplied specimens from Tunisia from at least 1895 up to 1915, and that they could be entered into the catalogues at dates considerably later than the collection date.

Sylvia cantillans moltonii Orlando, 1937, *Rivista italiana di Ornitologia* (n.s.) 7 p.213.

Type locality: "nidifica in Sardegna (e Corsica?)" [nesting in Sardinia (and Corsica?)].

Type: syntypes MSNM Av5916 (adult male, collected at Tortolì, Sardinia, on 10 April 1931), MSNM Av5917 (adult male, collected at Tortolì, Sardinia, on 10 April 1931), MSNM Av5918 (adult male, collected at Lanusei, Sardinia, on 24 June 1930), MSNM Av5919 (adult male, collected at Lanusei, Sardinia, on 7 June 1930), MSNM Av5943 (collected at Cagliari, Sardinia, on 16 May 1924), MSNM Av5952 (adult male, collected at Lanusei, Sardinia, on 10 August 1914, old number 23031), MSNM Av5954 (adult male, collected at Arbatax, Sardinia, on 7 July 1915, old number 23030), MSNM Av5960 (adult female, collected at Lanusei, Sardinia, on 29 July 1927), MSNM Av5962 (adult female, collected at Ilbono, Sardinia, on 15 April 1928), MSNM Av5963 (adult male, collected at Tortolì, Sardinia, no date), MSNM Av5966 (collected at Quartu S. Elena, Sardinia, on 25 October 1925), MSNM Av5967 (collected at Quartu S. Elena, Sardinia, on 23 September 1925) (Supporting Information Fig. S6).

Notes: in the short, original description no information is provided concerning the number of specimens examined (Orlando, 1937). Subsequently, in a longer article Orlando (1939) stated that he examined 16 specimens in his collection and another eight in the MSNM, all considered to represent the new taxon. He designed specimen no. 1664 (now MRT 1664) as type (i.e. a lectotype according to Art.74.5), and the other 15 specimens in his collection (now MRT 1665-1679) as paratypes (i.e. paralectotypes). The type status of these specimens has been accepted by Arnone & Orlando (1990).

However, after examining the correspondence between Orlando and Moltoni (then bird curator at the MSNM), which is kept in Moltoni's archive in the MSNM library, the situation appears much more complex. The original description was published in the July issue of *Rivista italiana di Ornitologia* and the short note is dated April 1937. A date no later than April is compatible with the time required for typesetting and printing the July issue and further confirmed by a letter from Orlando to Moltoni (9 March 1937: "... al mio desiderio di pubblicare un lavoro che ha carattere di urgenza. Soltan- [sic] chiarisco che intendevo alludere al 3° fascicolo del corrente

anno che, a quanto ho creduto di comprendere nella Sua precedente, sarà pubblicato fra due mesi e prima della sua assenza" [... my wish to publish a work with urgency. I would only clarify that I was suggesting the 3rd issue of current year that, as I understood from your previous [letter], it will be published in two months and before your departure]).

In the same letter Orlando affirms "Io ne ho esaminato della Sardegna, ma in piccolissimo numero ... Però non ne ho nessuna di questa provenienza nella mia raccolta ed ho già scritto per procurarmene." [I have examined some from Sardinia, but in little number ... However, I have none of this provenance in my collection and I already wrote to obtain some]. Indeed, the 16 specimens in the Orlando collection were supplied by Amalia Mameli Meloni, a dealer in natural history specimens based in Lanusei (Sardinia). The collection dates span from 18 April to 22 May 1937. When accounting the time needed to prepare and ship the specimens, none of these could have been available to Orlando at the time of writing his 1937 note and we conclude that none of them has a type status.

According to other letters, on 26 February 1937 Moltoni sent 19 specimens of the MSNM to Orlando, who acknowledged receipt on 3 March. Among these specimens, 12 are from Sardinia and they were returned to Moltoni on 3 January 1938 (the other seven specimens are from Lybia, Apulia, Dalmatia, Sahara). We verified in the MSNM catalogues that the museum indeed acquired 12 specimens from Sardinia before 1937 and all of them are still extant. All these must be considered syntypes. We assume that the reference to eight instead of 12 specimens from MSNM in Orlando (1939) is in error.

Both in letters and in the 1939 publication, Orlando refers several times to specimens examined in different museums and collections. However, the wording is usually ambiguous and it is not clear if, in addition to those from MSNM, Orlando ever examined any other Sardinian specimens. The two other collections mentioned are the "R. Museo" (i.e. Museo di Zoologia, University of Palermo) and the Whitaker collection (at that time in Palermo and now split between the National Museums Northern Ireland and the National Museums Scotland). However, none of these museums has any specimens from Sardinia that could be included in the type series (Lo Valvo & Massa, 2000; B. McGowen, A. Ross, Z. Timmons, D. Tosh, pers. comm.).

Sylvia inornata iberiae Svensson, 2013, *Bulletin of the British Ornithologists' Club* 113 p.244.

Type locality: "El Pardo, Madrid, Spain".

Type: holotype NHMUK 1934.1.1.249, adult male, collected at El Pardo, Madrid, Spain, on 24

May 1931. A picture of the holotype is available in Svensson (2013a).

Notes: this new taxon was proposed to differentiate the populations from Spain, southern France and north-west Italy from those in North Africa. Although we did not genotype the holotype, a

breeding individual, our specimens from mainland Spain were all collected during the breeding season and all belong to clade 3, making the name *iberiae* unquestionably available for this clade.

4. DISCUSSION

4.1. Systematics and phylogeography

The Subalpine Warbler complex represents a nice example of ongoing divergence among geographically structured populations showing varying degrees of divergence, suggesting that the lineages in the complex have reached different stages of the speciation process.

A geographically more complete sampling confirms the strong structuring of the *Sylvia cantillans* complex reported in a previous phylogeographic study (Brambilla *et al.*, 2008c) and sheds further light on the relationships between the five clades identified in the complex. In short, our work based on combined mitochondrial and nuclear evidences supports a three-species split in the *Sylvia cantillans* complex. This treatment was already hypothesized by Brambilla (2013) and suggested by Svensson (2013a,b), but our arrangement includes important differences at the subspecific level and in the nomenclatural rearrangement, following a critical evaluation of the available types.

Clade 3 - Western Subalpine Warbler

At the high end of the genetic divergence, clade 3 is isolated from all other lineages in both mitochondrial and nuclear markers. Mitochondrial distances from the other clades are very high (3.3-4.1% and 4.4-5.2%, *cytb* and *COI* genes, respectively) and comparable to those observed between full species (Helbig *et al.*, 1995; Hebert *et al.*, 2004; Pons *et al.*, 2016). The substantial lack of shared nuclear alleles is evident in the single intron as well in the multi-locus networks, and the inferred lack of gene flow with the other lineages supports the recognition of clade 3 as a full species level group, the Western Subalpine Warbler.

Genetic analyses of our small North African sample size (one breeding bird from Tunisia and five breeding birds from Morocco) suggest that the populations from the entire Maghreb belong to the same lineage, which is closely related to western European populations from Portugal, Spain, France and north-west Italy. Gene flow between European and North African populations likely followed a western way across the Strait of Gibraltar rather than the Strait of Sicily. This interesting result would need to be confirmed using more individuals. Many species belonging to diverse zoological groups occur on both sides of the Strait of Gibraltar while Italian-North African endemics shared across the Strait of Sicily are much more rare (Husemann *et al.*, 2014).

Considering birds, the biogeographical importance of the Strait of Gibraltar as a link between Europe and North Africa has been pointed out by several studies dealing with different species (e.g. *Galerida cristata*, Guillaumet *et al.*, 2008; *Muscicapa striata*, Pons *et al.*, 2016). Unlike the European population, we did not detect any sign of population expansion for the North African population. Such a difference suggests that these populations do not share the same demographic history. In a biogeographical perspective, it would be interesting to test whether the Maghreb could have played a role as a glacial refugium for the Western Subalpine Warbler.

Clades 1 and 2 - Moltoni's Warbler

At the opposite end, only a shallow distance separates clades 1 and 2 (1.0-1.2% in *cytb* and *COI*, respectively). The two mitochondrial lineages are geographically well separated and only a few breeding birds observed along the Tuscany coast proved to belong to the island clade 2 (Brambilla *et al.*, 2008a). Nonetheless, the two clades began to diverge recently and still constitute a single nuclear genetic pool, as indicated by the lack of structure in the single intron and in the multi-locus networks. Jointly, clades 1 and 2 are here recognised as a second species level group, the Moltoni's Warbler.

Clades 1 and 2 are well differentiated from the rest of the species complex not only genetically, but also according to phenotypic traits. These populations have distinct contact call and song, different moult strategy, later spring migration time and males can be separated by their pinkish ventral colouration (Gargallo, 1994; Shirihai *et al.*, 2001; Svensson, 2013a,b). In addition, they occur sympatrically with clade 4 in central-northern Italy and show different reaction to conspecific and heterospecific songs (Brambilla *et al.*, 2008a,b).

The neat mitochondrial separation between island and mainland populations might represent different evolutionary lineages, although no morphological and no nuclear genetic differences are known at present between the two groups. However, alternative hypotheses could not be excluded as explanation for such a mitochondrial pattern (reviewed by Toews & Brelsford, 2012). The same phylogeographic structure could be a simple by-product of sex specific dispersal strategy, with highly philopatric females and nuclear gene flow assured by more dispersive males (even if, in general, the opposite pattern is more common in passerine birds, Greenwood, 1982). Alternatively, retention of nuclear ancestral polymorphism due to recent divergence event (Zink & Barrowclough, 2008) may also explain the mito-nuclear discrepancy. Until more evidence has become available, we favour a conservative approach and suggest to treat these populations as a single, monotypic species.

Clades 4 and 5 - Eastern Subalpine Warbler

Clades 4 and 5, representing eastern populations (from central Italy eastwards), display an intermediate case of population divergence. Mitochondrial clades 4 and 5 are clearly apart, with divergence values slightly higher (1.4-1.6% in *cytb* and *COI*, respectively) than those obtained for insular *vs.* mainland Moltoni's Warblers. Although some intron alleles are shared by the two mitochondrial lineages, a significant proportion of private alleles suggests a reduced gene flow between the two groups and a well-advanced lineage sorting. The multi-locus networks clearly show that the two clades are closely related, but most individuals segregate on different sides of the network branch. Although we recognise that the two populations are close to the speciation threshold, weighting the molecular data, the difficult diagnosability of these two groups (Brambilla *et al.*, 2010), and the fact that the two interbreed where they meet at different sites of the Adriatic region (Brambilla *et al.*, 2008; our unpubl. data), we prefer a more conservative approach and we assign clades 4 and 5 to a polytypic species level taxon, the Eastern Subalpine Warbler. Further molecular and bioacoustics data might shift the balance to a different taxonomy (e.g. they could be semispecies *sensu* Helbig *et al.*, 2002).

We remark also that in clade 5 three specimens collected in Lesvos (Greece) are basal and distinct from the rest of the clade, including six other individuals obtained on the same island, at the same time. Due to the small sample, we are not able to discuss this pattern further, but we are confident that it is not an artefact due to the inclusion of nuclear pseudogenes, since both mitochondrial genes support the same signal, the sequences from these specimens align perfectly with the rest of the dataset, all mutations are synonymous substitutions, mostly restricted to the third codon position. To determine if these three specimens are indicative of a geographic structuring in the easternmost populations of the clade or the result of the co-occurrence of distinct mitochondrial haplogroups, requires more inclusive sampling.

4.2. Taxonomic and nomenclatural issues

The reappraisal of all original descriptions of names applied to the *Sylvia cantillans* complex, the study and genotyping of surviving type specimens and the use of archival documents provided a sound framework to revise the nomenclature of this complex.

From the original catalogue written by Bonelli we have been able to ascertain that the type specimen of *Sylvia subalpina* Temminck, 1820 was collected near Turin on 6 September 1819 and disposed of in 1827 due to insect damage. However, while Bonelli affirmed that the specimen was a male, Temminck (1820,a,b) stated that it was a female in spring plumage.

The collection date indicates that the holotype was collected during the migratory period and Turin lies between the ranges of Moltoni's and Western Subalpine Warblers. In addition, the

Eastern Subalpine Warbler also occurs in Piedmont as a vagrant (Pavia & Boano, 2009). All these factors complicate the identification of the lost type.

We assume that Bonelli, a skilled ornithologist who examined the specimen in flesh, was able to correctly identify the sex as male. The colour description and the plate published by Temminck (1820a,b) are more congruent with the male plumage, in particular the dorsal ("Sommet de la tête, joues, nuque, dos et scapulaires d'un joli cendré pur" [crown, cheeks, neck, back and scapulars of a pure ash colour]) and ventral colour ("gorge, devant du cou, poitrine, flancs et abdomen d'une belle couleur vineuse" [throat, front of the neck, chest, flanks and abdomen of a nice vinaceous colour]), while they would be too saturated for a female.

The vinaceous colour suggests that the lost type was more likely to have been a Moltoni's Warbler (clades 1 and 2), excluding males of both Eastern and Western Subalpine Warblers, where the ventral side is invariably described as red-brick (Svensson, 2013a,b). However, the molecular results indicate that Moltoni's Warbler comprises two mitochondrial lineages for which no morphological differences have been identified, and Brambilla *et al.* (2012) demonstrated that the Subalpine Warblers *s.l.* have a complex migration pattern, with different lineages migrating together and co-occurring at the same stop-over site.

In agreement with Art. 75, in order to stabilize the nomenclature and objectively link the name *subalpina* to the mainland populations of Moltoni's Warbler, we here designate the specimen MSNM Av37427 as the neotype of *Sylvia subalpina* Temminck, 1820 (zoobank urn:lsid:zoobank.org:pub:8C077808-E903-4E40-82A1-E365F6630D30). It is a road killed adult male found by GB and Gary Voelker on 9 June 2018 at Pocapaglia (44°43'N, 7°53'E), in the central hills of Piedmont, 40 Km SE of Turin. It has been prepared as a study skin by GB (field number GB 1365) (Fig. 7). This bird was certainly breeding considering the date and the gonad development (testis 6,5x5 mm) and the species is a rather common breeding bird in the area (Mingozzi *et al.*, 1988).

All conditions mandated by Art. 75.3 are here met, in particular: the mitochondrial sequences obtained from the neotype (Genbank Accession Numbers MN642448 and MN642344) confirm that it belongs to clade 1, and the uniform vinaceous shade extending from throat to flanks is diagnostic of the Moltoni's Warbler, excluding the other species in the complex (Art. 75.3.2); the neotype plumage colours match the plate published by Temminck (1820b) (Art. 75.3.5); it comes from the Turin area (Art. 75.3.6); it has been deposited in the Museo Civico di Storia Naturale, Milan, with the number MSNM Av37427, and a tissue sample preserved in ethanol is kept in the ornithological collection of the Museo Civico di Storia Naturale, Carmagnola, with number MCCI 5150 (Art. 75.3.7).

Description of: the neotype (capitalized colour names follows Ridgway, 1912): it has a Medium Dark Plumbeous front, Dark Graysh Brown head, nape and mantle, narrow Russet-Vinaceous orbital ring, White sub-moustachial stripe narrow, throat and breast between Vinaceous and Avellaneous, and this colour extends to lower flanks fading in the central whitish belly. The wings are Olive Brown fringed Buffy Brown, the rectrices being Dusky Brown with large white portions on the outermost feather and a whitish rounded spot on the tip of inner web of the penultimate feather. The pointed bill has a paler base. Legs pale. Wing length (max. chord) 63 mm, tail length 54 mm, tarsus 19 mm, weight 9.1 gr.

As expected, the phylogenetic analysis confirmed that the name *Sylvia cantillans moltonii* Orlando, 1937, belongs to the insular populations of Moltoni's Warbler, with both genotyped syntypes falling in clade 2, together with the other specimens from Sardinia and Corsica. However, we demonstrated that the name itself was actually established on a totally different group of syntypes (12 specimens in MSNM) and that none of those indicated by Orlando (1939) could claim a type status.

Instead, the reidentification of *Sylvia cantillans inornata* Tschusi, 1906, is a totally unexpected result with deep nomenclatural implications. Although accepted as valid and consistently applied to North African populations (Table 1), the name *inornata* actually applies to clade 2 as well, as indicated by the lectotype haplotype.

The ventral colour of specimens from North African populations are invariably described as red, orange or brick, at least since Hartert (1910: "Kehle und Körperseiten mehr rotbraun, fast zimtrot" [throat and body sides more reddish brown, almost cinnamon red]) and Vaurie (1959: "Male somewhat more brick red below, less pinkish"). However, in the original description, Tschusi (1906a) states clearly "Kinn und Kehle sehr schwach weinrötlich" [Chin and throat very pale wine red], a colour description that matches well with the "belle couleur vineuse" [nice vinaceous colour] in Temminck's description of *subalpina*. When one of us (DZ) examined the type series of *inornata* at the ZSM, he was immediately surprised by the ventral colour. Although no other specimens from North Africa were available for direct comparison in the ZSM, the genotyping of the *inornata* lectotype confirmed that it did not belong to the North African populations, as traditionally assumed, but matched phenotypically similar birds in clade 2. The type series was collected in May (no day specified) and migrating Moltoni's warblers can actually be found during all May (our data). It is thus clear that those collected in Tunis were migrants and not breeding locally, that the types have never been re-examined since and that the name *inornata* was applied relying merely on the collection locality.

With the recognition of the Moltoni's Warbler as a monotypic species, the names *Sylvia subalpina inornata* Tschusi, 1906, and *Sylvia cantillans moltonii* Orlando, 1937, are here treated as

junior synonyms of *subalpina* Temminck, 1820. If island and mainland populations should be deemed to represent distinct taxonomic units, the name *inornata* will take precedence for the island populations.

However, we remark here that despite its continuous use for the North African populations, Tschusi's name is actually preoccupied by a much older senior homonym, *Sylvia inornata* Latham, 1801 (Latham, 1801a: I p.liv). The latter is based on Latham's "Terrene Warbler" (Latham, 1801b: p. 248 no.30), in turn based on the Watling Drawing no.161 (Mathews & Iredale 1923), an unidentified meliphagid, possibly referable to an Australian *Melithreptes* honeyeater (Gray, 1843). Latham's name has been used only occasionally as a valid name by a few early 19th Century authors (e.g. Stephens, 1817: p.696; Vieillot in Deterville, 1817: p.600; Vieillot, 1821: p.409; Drapiez in Bory de Saint-Vincent, 1822: p.293) and subsequently forgotten. In contrast, the continuous use of *Sylvia subalpina inornata* Tschusi, 1906 meets the requirements of Art. 23.9.1.1 and 23.9.1.2 of the ICZN (1999), i.e. used as a valid name in at least 25 works by at least 10 authors in the last 50 years over a span of at least 10 years. Under these circumstances, if a distinct subspecific rank is granted to the island populations of Moltoni's Warbler, Tschusi's name should be declared a *nomen protectum*, taking precedence over *Sylvia inornata* Latham, 1801, a *nomen oblitum*.

The species corresponding to clade 3, the Western Subalpine Warbler, has a continuous distribution around the western side of the Mediterranean basin, from Tunisia to Morocco, Spain to the westernmost end of Italy. Although the intraclade genetic distance is low (0.2%), our population genetics results suggest that a significant population structure separates African vs. European specimens. With the transfer of the name *inornata* to a different clade, *Sylvia inornata iberiae* Svensson, 2013 remains the only available name. Although the *iberiae* holotype has not been genotyped, its breeding status is indicated by a remark on the label ("Breeding by the river") and all our Spanish specimens fall into clade 3 in the phylogeographic analysis. This name was introduced to differentiate the Spanish-French population in comparison to North African birds (Svensson, 2013a).

The description of *iberiae* complies with the Code and this name is nomenclaturally available. It thus becomes the valid name for clade 3 as a whole. However, due to lack of morphological divergence and low genetic distinctiveness, we express doubts that North African and European populations should be recognised as distinct taxonomic units at the subspecies level and, at present, a new name seems unwarranted for the North African birds. The purported differences between North African and European specimens indicated by Svensson (2013a) appear to be extremely weak: 1- the main stated difference is the colour ("being less yellow-tinged above and below, which difference is particularly obvious in series"), but no quantitative analysis is presented, and a colour

gradient has been suggested, with southern Spanish individuals becoming increasingly similar to African breeders (Shirihai *et al.*, 2001); 2- morphometric differences are vaguely stated without a proper statistical comparison, and are apparently minute ("*iberiae* is on average very slightly smaller, although differences are miniscule and unhelpful for identification"); 3- the new taxon is based on the study of 58 and 57 specimens of *iberiae* and *inornata sensu* Svensson (2013a), respectively (see also Tab. 1 in Svensson, 2013b). However, the majority of these were collected during the migration period (Table 7). The species group has a complex migration pattern, with birds belonging to different clades migrating together and captured at the same sites (Brambilla *et al.*, 2012). In addition, the phenotypic identification of individual specimens in the complex remains challenging, with 9% of genotyped birds misidentified and 19% considered as intermediate/doubtful when ringed individuals are examined in hand (Brambilla *et al.*, 2010). The difficulties in separating individual specimens between the two subspecies is acknowledged by Svensson (2013a) himself ("at least 75% differ diagnosably, probably many more"). It seems to us that the only specimens available for a reliable comparison among those listed in Tab. 1 of Svensson (2013b) should be those collected during the breeding period and well outside the migration. When specimens collected before 15 May and after 31 July are excluded, only 11 North African and 8 European breeding birds remain, representing a much smaller sample than stated by Svensson (2013b) (Table 7). Attributing any other individual to the North African or the European breeding population seems to us either circular reasoning, if based on the supposed colour differences between the two groups, or totally unwarranted, if based on capture locality alone. For these reasons, until more robust analyses on breeding birds only are provided, we reject the recognition of any subspecies in clade 3, which will thus become a monotypic species named *Sylvia iberiae*.

Although the *Sylvia cantillans* neotype has not been genotyped, two breeding individuals obtained at the restricted type locality (Ficuzza, Sicily) are included in our phylogenetic reconstruction and all evidence indicates the name *Sylvia cantillans* Pallas, 1764 applies unquestionably to clade 4. We refer to the same clade the junior synonyms *Sylvia leucopogon* Schinz, 1821 and *Sylvia leucopogon* Meyer, 1822. By re-examining the original descriptions and from archival records, we conclude that the two names are not only absolute homonyms, but also absolute synonyms, both being based on the same series of specimens from Sicily obtained by Heckel in 1820.

The lectotype of *Curruca albistriata* Brehm, 1855, was collected in Egypt and it must have been a migrant, because the species does not breed there. In plumage, it agrees well with the birds from the Balkans. The genotyping confirms its attribution to clade 5.

The clades 4 and 5 clearly represent an intermediate stage in the speciation process, forming distinct mitochondrial lineages with some nuclear gene flow as indicated by the nuclear networks.

Morphologically, most individuals in the two groups are fairly well identifiable, differing in size and plumage colour, especially in males, which are typically darker and with a more contrasting white belly in eastern birds (*albistriata*) than in Italian breeders (*cantillans*) (Shirihai *et al.*, 2001). However, a few individuals show more nuanced plumage coloration and can be misidentified even when examined in hand (Brambilla *et al.*, 2010), and nearly all measurements show a certain degree of overlap. Although differences exist in songs and, especially, in calls, no quantitative comparisons nor playback experiments have been carried out to test if any acoustic isolation may exist. We consider that the evidences available at present are conflicting, and we recommend following a conservative approach, treating the two clades as a single polytypic species, *Sylvia cantillans*, with the subspecies *cantillans* and *albistriata*, but we recognise that according to other approaches or criteria for species delimitation, the arrangement of these two taxa might be different.

5. CONCLUSIONS

The Subalpine Warbler complex nicely illustrates how divergence took place even over relatively limited geographic extents, further confirming the importance of the Mediterranean basin as a biodiversity hotspot within Europe (Marchese, 2015) and its role in shaping European avifauna (e.g. Perктаş *et al.*, 2019). The pattern of divergence and geographical structuring in the *Sylvia cantillans* complex shows some remarkable similarities with those reported for other complexes of avian species in the Mediterranean region, and in particular the role of glacial refugia played by the Western Mediterranean Islands (Corsica, Sardinia, Balearics) (e.g. *Certhia familiaris*, Pons *et al.*, 2015; *Muscicapa striata*, Pons *et al.*, 2016, *Periparus ater*, Tritsch *et al.*, 2018).

Our study has been made possible by the integration of modern molecular analyses with the nomenclatural framework supplied by natural history collections and archives, which highlights once more the critical role played by museums in modern biodiversity investigation. We also emphasize the importance of referring to type specimens in taxonomic revisions, even for species belonging to apparently well-known regions like Europe.

In conclusion, we recommend the recognition of three species in this complex:

Sylvia subalpina Temminck, 1820 (Moltoni's Warbler), monotypic

north-central Italy, Corsica, Sardinia, Balearics

Synonyms: *Sylvia subalpina* Temminck, 1820

Sylvia subalpina inornata Tschusi, 1906

Sylvia cantillans moltonii Orlando, 1937

Sylvia iberiae Svensson, 2013 (Western Subalpine Warbler), monotypic

North Africa, from Tunisia to Morocco, Iberia, southern France, extreme north-west Italy

Synonyms: *Sylvia inornata iberiae* Svensson, 2013

Sylvia cantillans (Pallas, 1764) (Eastern Subalpine Warbler), polytypic

Sylvia cantillans cantillans (Pallas, 1764)

Southern Italy, Sicily

Synonyms: *Motacilla cantillans* Pallas, 1764

Sylvia leucopogon "Heckeli" Schinz, 1821

Sylvia leucopogon "Heckeli" Meyer B, 1822

Sylvia cantillans albistriata (Brehm CL, 1855)

Extreme north-east Italy, Balkans, Greece, western Turkey

Synonyms: *Curruca albistriata* Brehm CL, 1855

ACKNOWLEDGEMENTS

We are grateful to the institutions that provided tissue samples used in this study or granted us access to the specimens in their care: American Museum of Natural History, New York; Istituto Superiore per la Protezione e la Ricerca Ambientale, Ozzano dell'Emilia; Museo Civico di Storia Naturale, Carmagnola; Museo Civico di Storia Naturale, Milano; Muséum National d'Histoire Naturelle, Paris; Museo Regionale di Terrasini, Terrasini; Museum of Natural History, Belgrade; The Natural History Museum, Tring; Naturalis Biodiversity Center, Leiden; Naturhistorische Museum, Vienna; Zoologische Staatssammlung München, Munich.

Jean-Claude Thibault kindly supplied some feather samples from Corsica collected under a "Centre de Recherches sur la Biologie des Populations d'Oiseaux" program (Muséum National d'Histoire Naturelle) directed by Georges Oliosio.

For accessing archival documents and for information concerning historical specimens we are grateful to: L. Iazzetti (Accademia delle Scienze, Turin); P. R. Sweet (American Museum of Natural History, New York); L. Frattarolo (Biblioteca Nazionale, Turin); A. De Felice (Biblioteca Reale, Turin); P. Passerin d'Entrèves and D. Grigion (Dipartimento di Scienze della Vita e Biologia dei Sistemi, University of Turin); R. Lindner (Haus der Natur, Salzburg); C. Gouraud (Musée George Sand et de la Vallée Noire, La Châtre); G. Bardelli (Museo Civico di Storia Naturale, Milano); E. Gavetti and M. Spini (Museo Regionale di Scienze Naturali, Turin); F. Lo Valvo

(Museo Regionale di Terrasini, Terrasini); D. Tosh and A. Ross (National Museums Northern Ireland, Holywood); B. McGowen and Z. Timmons (National Museums Scotland, Edinburgh); R. Prÿs-Jones and A. Harding (The Natural History Museum, Tring); P. Kamminga, S. van der Mije and J. Jansen (Naturalis Biodiversity Center, Leiden); H.-M. Berg and A. Schumacher (Naturhistorische Museum, Vienna); G. Mayr (Naturmuseum Senckenberg, Frankfurt am Main); B. Gharaibeh (University of Pittsburgh); D. Hansen and M. Schenkel (Zoologische Museum, University of Zurich).

BirdLife International and Handbook of the Birds of the World kindly supplied the shapefiles with the species distribution.

We would like to thank R. Prÿs-Jones and two anonymous reviewers for comments and suggestions that improved our manuscript.

This work was in part supported by ‘Service de Systématique Moléculaire’ (UMS2700 Outils et Méthodes de la Systématique intégrative, MNHN). We acknowledge the support by a SYNTHESYS grant to DZ by the European Community - Research Infrastructure Action under the FP6 Structuring the European Research Area Program (AT-TAF-3163). MP was supported by Torino University Grants ex 60% 2017 and 2018.

<i>S. melanothorax</i>		from Genbank			
<i>S. mystacea</i>		from Genbank			
<i>S. undata</i>		MNHN 2000.1650			

Table 3. Mitochondrial *p*-distances between clades (below the diagonal) and within clades (along the diagonal, underlined) for the the cytochrome *b* and COI genes.

cytb	Clade 1	Clade 2	Clade 3	Clade 4	Clade 5
Clade 1	<u>0.19073</u>				
Clade 2	0.96361	<u>0.08038</u>			
Clade 3	4.05734	3.81162	<u>0.22211</u>		
Clade 4	4.70475	4.38894	3.63053	<u>0.16641</u>	
Clade 5	4.11009	3.79969	3.30734	1.60175	<u>0.2197</u>

COI	Clade 1	Clade 2	Clade 3	Clade 4	Clade 5
Clade 1	<u>0.13239</u>				
Clade 2	1.16512	<u>0.06173</u>			
Clade 3	4.30556	4.79167	<u>0.29646</u>		
Clade 4	3.5094	3.34877	4.36378	<u>0.22513</u>	
Clade 5	4.28241	4.16667	5.17747	1.35066	<u>0.22742</u>

Table 4. Fst values between mitochondrial clades within the tree main lineages calculated for two nuclear introns (FIB 5 and GAPDH) and the combined mitochondrial data set (cytochrome *b* and COI, 1738 bp). S=Significant; NS=Non Significant.

	bFib5	GAPDH	mtDNA
clades 1/2 (N Italy/Islands)	Fst = - 0.01 P = 0.54, NS	Fst = - 0.01 P = 0.48, NS	Fst = 0.87 P < 0.001, S
clade 3 (Europe/Maghreb)	Fst = 0.10 P = 0.10, NS	Fst = 0.24 P < 0.001, S	Fst = 0.58 P < 0.001, S
clades 4/5 (S Italy/Balkans)	Fst = 0.32 P < 0.001, S	Fst = 0.27 P < 0.001, S	Fst = 0.87 P < 0.001, S

Table 5. Genetic diversity indices of the combined mitochondrial data set (1738bp, cytb + COI). Haplotype diversity (H), nucleotide diversity (N), Mean number of pairwise differences (Pi).

	Clade 1	Clade 2	Clade 3 (Europe)	Clade 3M (Maghreb)	Clade 4	Clade 5
No. of gene copies	20	15	15	6	23	21
No. of substitutions	18	27	15	8	20	21
Pi	2.8	1.3	2.1	4.1	3.2	3.7
H	0.94	0.84	0.85	0.73	0.92	0.85
N	0.002	0.002	0.001	0.002	0.002	0.002

Table 6. Tajima's D and Fu's statistics of population expansion obtained for each mitochondrial clade based on the combined mitochondrial data set (cytochrome b and COI, 1738 bp)

	Clade 1	Clade 2	Clade 3 (Europe)	Clade 3M (Maghreb)	Clade 4	Clade 5
Tajima's D test	-1.70	-2.25	-2.16	0.95	-1.53	-1.37
p-value	0.032	0.002	0.003	0.82	0.049	0.069
Fu's FS test	-7.53	-1.95	-4.24	2.47	-8.45	-2.68
p-value	0.001	0.13	0.003	0.89	0.001	0.091

Table 7. Number of specimens examined by Svensson (2013a, b) from North Africa ("*inornata*") vs. Iberia-France ("*iberiae*") and number of specimens collected outside the migration period (16 May-31 July). Acromomys: AMNH American Museum of Natural History, New York, USA; MNHN Muséum National d'Histoire Naturelle, Paris; NHMUK The Natural History Museum, Tring; NRM Naturhistoriska Riksmuseet, Stockholm; RMNH Naturalis Biodiversity Center, Leiden; ZFMK Zoologisches Forschungsmuseum Alexander Koenig, Bonn; ZMUC Zoological Museum, University of Copenhagen. * include a female collected on 10 May with large ovary drawing on the label.

Museum	" <i>inornata</i> "	" <i>iberiae</i> "	breeding " <i>inornata</i> "	breeding " <i>iberiae</i> "
NHMUK	19	31	5 ♂, 2 ♀*	6 ♂
AMNH	19	6	1 ♂, 2 ♀	-
MNHN	12	10	-	1 ♂
NRM	3	1	1 ♂	-
RMNH	1	7	-	1 ♂
ZFMK	2	-	?	-
ZMUC	1	1	?	?
Totals	57	56	11 (7 ♂, 4 ♀)	8 (8 ♂)

Figure 1. The Maximum Likelihood tree obtained from the mitochondrial dataset (cytb+COI). The bootstrap support values are indicated at the node. Numbers on branches refer to the clades discussed in the text. Samples obtained from breeding specimens are highlighted with coloured dots, matching the clade coding in the map (Figure 2). clade distribution and proposed taxonomy on the right. The tree has been edited in MrEnt v.2.5 (Zuccon & Zuccon, 2014).

Figure 2. Breeding range of the Subalpine Warbler *Sylvia cantillans* complex and origin of samples used in the phylogenetic analysis. The colour code matches the clades recovered in the

mitochondrial tree (dots: breeding specimens; triangles: status unknown or migrants; bicolored dots: localities where specimens of two clades were recorded in syntopy). Collection localities of types are indicated by arrows and numbers: 1 *Sylvia inornata iberiae*; 2 *Sylvia subalpina*; 3 *Sylvia cantillans moltonii*; 4 *Sylvia subalpina inornata*; 5 *Motacilla cantillans*; 6 *Sylvia leucopogon*; 7 *Curruca albistriata* (approximate). The species range shapefile has been supplied by BirdLife International and Handbook of the Birds of the World (2018).

Figure 3. A, B: Minimum Spanning Networks showing relationships among GAPDH (A) and bFib5 (B) alleles for the Subalpine Warbler *Sylvia cantillans* complex, respectively. The colour code matches the clades recovered in the mitochondrial tree; circle size is proportional to the allele frequency. C: Multilocus networks obtained using standardized genetic distances of the two nuclear loci (GAPDH and bFib5). The colour code matches the clades recovered in the mitochondrial tree.

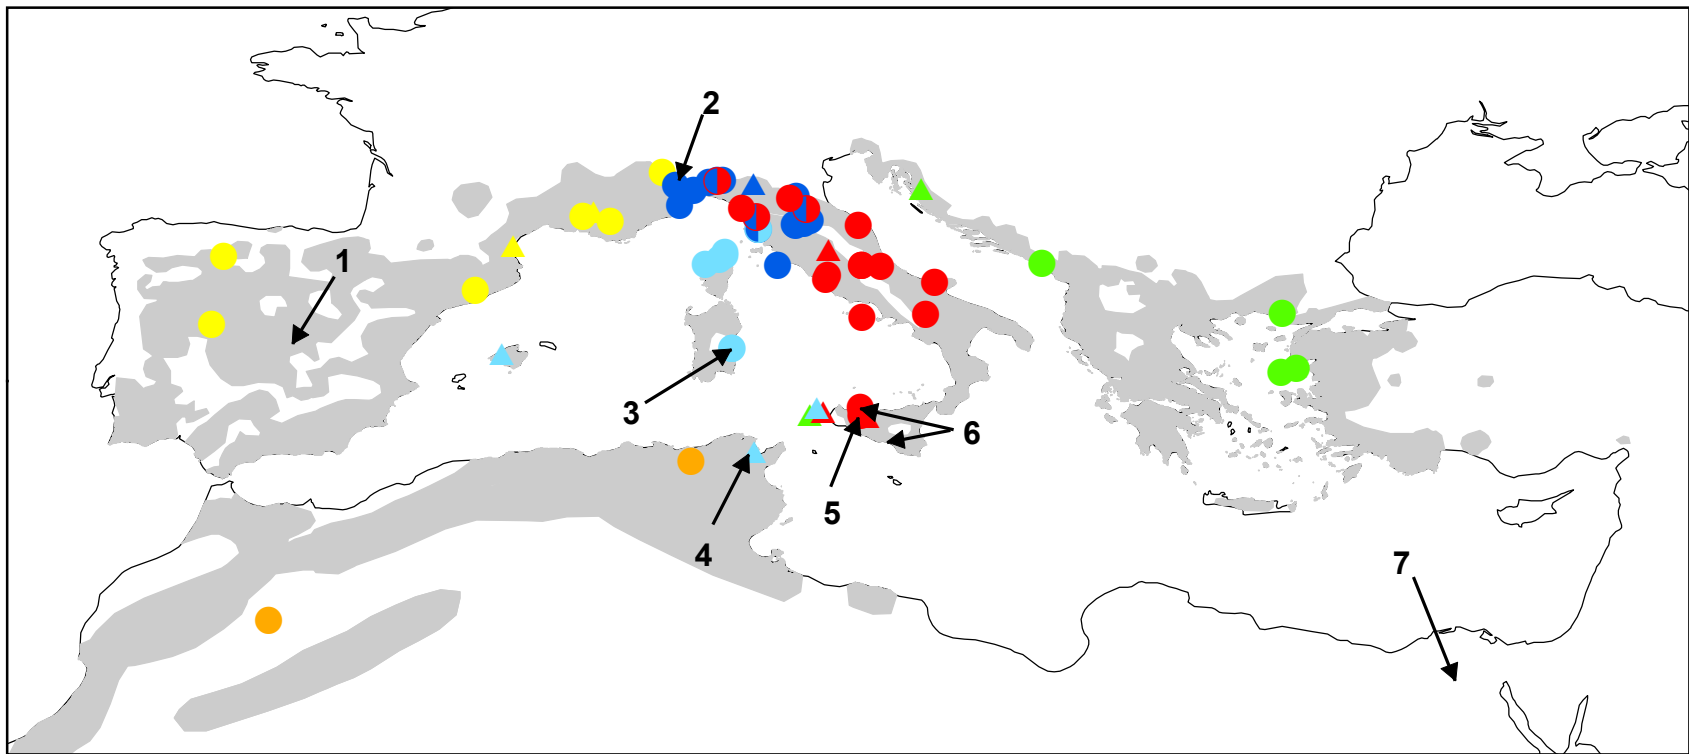

Figure 4. A. Minimum Spanning Network showing relationships among AK1 alleles. B. Multilocus networks obtained using standardized genetic distances of the three nuclear loci (AK1, GAPDH and bFib5). The colour code matches the clades recovered in the mitochondrial tree.

Figure 5. Bonelli's catalogue entry for the type specimen of *Sylvia subalpina* Temminck, 1820, in *Catalogo numerico degli Animali Vertebrati del R. Museo* [Numerical catalogue of vertebrate animals of the Royal Museum].

Figure 6. Comparison between Schinz's and Meyer's descriptions of *Sylvia leucopogon* (left and right, respectively). Word groups identical in both texts are highlighted in colour. Images from the Biodiversity Heritage Library. Digitized by Naturalis Biodiversity Center (Schinz) and Smithsonian Libraries (Meyer). | www.biodiversitylibrary.org

Figure 7. Neotype of *Sylvia subalpina* Temminck, 1820, MSNM Av37427, ventral (A), lateral (B), and dorsal (C) view. The images were calibrated with the Xrite ColorChecker.

Individuo già in catt. stato, e questo per non essersi
potuto debit. scorticare, tarlatosi in 1826 e riformato
in 1827 con un individuo similiss.o ed unico preso
a Domus de Maria presso Cagliari il 21 aprile 1828.

[male 6 september 1819: near Turin.
Specimen already in poor conditions, and this for not having
been properly skinned, moth damaged in 1826 and disposed of
in 1827 with a very similar and unique specimen, taken
at Domus de Maria, near Cagliari on 21 April 1828]

Weißbärtiger Sanger. Sylv. Leucopogon.
Heckeli.

Schnabel gerade, braun, der Unterschnabel heller, am Grunde gelblich, der Augensterne orangefarbig; Fue brunlichgelb. Kopf und Oberkorper aschgrau, bleifarbig, auf dem Rucken mit leichtem, brunlichem Anfluge. Zu beyden Seiten der Kehle am Grunde des Unterschnabels ein weier Streifen; Kehle, Vorderhals und Brust hellrostfarbig, der ubrige Unterleib wei, die Seiten rostfarbig angefliegen, Schenkel rostfarbig; Flugel braun, die uern Fahnen schmal, gelbwei eingefat. Schwanz braun, die uerste Feder nur am Grunde braun, das ubrige wei, die zweite mit weier Spitze, die dritte mit einem dreyeckigen, weien Fleck. Lange des ganzen Vogels 4 Zoll 7 Linien. In Sizilien.
